language), then the sceptical move can be met. For this is something which no one, and hence no sceptic, can properly think that they doubt. Hence the most robust transcendental arguments concern themselves merely with the preconditions of there being thought or language at all. Examples are (again) the Private Language Argument, or Davidson's argument that there is only one conceptual scheme. The next possible point of weakness after the initial assumption is the discovery of its necessary conditions. Obviously this must not have a purely observational basis. The argument that people could not think without brains - we think, hence we have brains, hence the external world exists - would not be an effective answer to scepticism. So the arguments have to be (at least relatively) a priori.

Some people have therefore held that transcendental arguments may only draw out the purely conceptual, or analytic, consequences of their initial assumptions. This gives them better security against scepticism but makes their chances of reaching interesting conclusions rather slim. Others have held, rather more ambitiously, that the connections do not need to be narrowly analytic: transcendental arguments show the necessary conditions for having thoughts. Therefore, if the having of one kind of thought is a necessary condition for having another kind of thought, this will be good enough, even if the contents of the thoughts themselves are not analytically connected.

3 Further criticisms

In transcendental arguments, necessary conditions are often demonstrated by discovering the unique conditions which enable some kind of thought to be had. Yet it has been claimed, most prominently by Stefan Körner (1969), that the uniqueness of a conceptual structure cannot be established. Uniqueness, he says, could only be demonstrated by the elimination of all possible rivals. Yet although we may eliminate all rivals that occur to us, there may always be a possibility that we might have overlooked or might not be able to envisage. Other people have similarly claimed that, at best, we can only describe how we currently think, or the limits of currently imaginable alternatives. However, neither of these can show how we must think; they cannot demonstrate the necessary conditions of thought.

Another criticism is that, even if it can be shown what we must think, this will not defeat scepticism. Defeating scepticism demands a demonstration that we are justified in thinking that our beliefs show how things actually are. However, showing that we must think something does not show that the thought is correct - a necessary illusion is still an illusion. The force of this criticism depends on the kinds of necessary conditions derived in transcendental arguments. If some matter of fact is shown to be a necessary condition for having thoughts, then it does not apply. However, in modern arguments, the necessary conditions derived for having one kind of thought are frequently other kinds of thought. For example in the Strawson argument discussed above in §1, it is belief in other people's pains that is the required presupposition. It can be objected that this is insufficient to answer scepticism (in this case about other minds) since the crucial point is not whether we have to believe that others have pains, but, rather, whether this belief is correct.

A version of this objection is the one which Stroud mounts against Strawson and others in his highly influential paper about transcendental arguments (1968). This is his claim that transcendental arguments need a version of the Verification Principle in order to work (see Meaning and verification). However, Stroud continues, if we are entitled to presuppose the Verification Principle, then transcendental arguments are not needed, since the Verification Principle by itself will do the anti-sceptical work. The principle shows that it makes no sense to suppose that our best-verified beliefs might not be true. Analogously, it can show that it makes no sense to suppose that beliefs that we must have are not true. However it is the verificationist assumption which is doing the deadly anti-sceptical work, not the transcendental argument which gets us from belief to necessary belief. Therefore the route through necessary belief is superfluous; transcendental arguments are either redundant or invalid.

Alternatively, the transition from what we (have to) believe to how things actually are can be made by shrinking the distance between them. A supposition of idealism would do this; so that in the end we do not distinguish between the structure of thought and an independent, real world waiting to be described. In Kant, some kind of idealism was required in order to make the transcendental arguments work, and it has been suggested by Bernard Williams (1973) and others that this also applies to modern users of transcendental arguments. However, some modern users would not take this to be a criticism (see Idealism; Realism and antirealism).

Translators

Translators played a crucial role in the history of medieval philosophy. Since multilingualism was generally restricted to places in which a direct contact between different languages was possible, such as Byzantium, the Near East, southern Italy or Spain, the dissemination of knowledge into foreign cultures was mainly brought about by means of translation. In this conversion process various kinds of writings were involved, including the Bible, the Qur'an and liturgical and hagiographic works as well as literary and historiographic texts.

1 Early Greek-Latin translations

The tradition of Greek-Latin translations of philosophical and scientific texts goes back to Cicero, whose philosophical works contain some translated fragments (for example, of Plato's *Timaeus*), but consist for the greater part of free adaptations of some contemporary Greek models. The practice of both translation and paraphrase was continued by early Christian writers such as Marius Victorinus and Ambrose (see Patristic philosophy). As for Plato's *Timaeus*, the greater part of it was known to medieval thinkers through the Latin translation and commentary of Calcidius in the fourth/fifth century.

The famous debate over translation *ad verbum* (according to the verbal expression) and *ad sensum* (according to the meaning) also originated in Roman times. Jerome in the fourth century, following Cicero, was a representative of the latter method but defended literal translation when a highly authoritative text such as the Bible was at issue. Boethius in the sixth century adopted the same position with respect to the works of a renowned philosopher such as Aristotle: he translated 'word for word' the *Categories*, *De interpretatione*, *Prior Analytics*, *Topics* and *Sophistici Elenchi*, as well as Porphyry's *Isagoge* (see Porphyry). Boethius' translation strategy was followed in the Carolingian Renaissance by Johannes Scottus Eriugena, who made the Neoplatonism of the Greek Fathers accessible to Latin readers (see Carolingian Renaissance).

2 The science of the Arabs

The twelfth century was an age of revival in European science and philosophy. This cultural phenomenon was, to a large extent, a consequence of the appearance of Latin translations of a number of Greek works, and also of some writings of the Arabs in which Greek science had been incorporated and developed. The initiator of this movement was Constantine the African, a monk of Monte Cassino in the second half of the eleventh century. He was a contemporary of Alfanus, archbishop of Salerno, who translated from Greek (under the title *Premnon physicon*) the treatise *On the Nature of Man* by Nemesius of Emesa. Constantine wrote several Latin versions of Arabic works, or of Arabic translations from Greek, on medicine, the most influential of which was the *Pantegni*, an adaptation of Haly Abbas' *Kitab al-malaki*.

An intriguing personality is Adelard of Bath, active in the first half of the twelfth century; his translations include the *Elements* of Euclid, the *Astronomical Tables* of al-Khwarizmi and the *Shorter Introduction to Astronomy* by Abu Ma'shar, and yet he does not seem to have had a profound knowledge of Arabic. Probably these versions were made with the collaboration of Adelard's teacher, the Spanish Jew Petrus Alfonsi. It was actually in Spain that most Arabic-Latin translations originated in the course of the twelfth century. Important translators were John of Seville and Hermann of Carinthia, both of whom produced Latin versions of Abu Ma'shar's *Greater Introduction* (in 1135 and 1140), and Hugh of Santalla, who shared with his contemporaries a strong interest in astronomy and astrology.

3 The *Aristoteles Latinus*

In the second half of the twelfth century, the flourishing centre of Arabic-Latin translations was Toledo. It was here that Dominicus Gundissalinus, with the help of the Jewish scholar Avendauth, translated into Latin some parts of Avicenna's *Kitab al-shifa'* (see Ibn Sina). Gerard of Cremona, probably the most prolific of all medieval translators, also worked in Toledo. Apart from his Latin translations of scientific works in almost every field, Gerard made a substantial contribution to the *Aristoteles Latinus*, the medieval Latin version of Aristotle's works: *Posterior Analytics*, *Physics*, *On the Heavens*, *On Generation and Corruption*, *Meteora* I-III and the pseudo-Aristotelian *Liber de causis* (see Aristotelianism, medieval; Liber de causis). Meanwhile, probably before 1150, the first two of these works as well as *On the Heavens*, some of the *Parva naturalia* and *Metaphysics*, had

been translated directly from Greek by James of Venice. Also known as 'Iacobus Veneticus Grecus', this translator probably lived in Byzantium for at least some time, like his contemporary Burgundio of Pisa, who produced a new version of Nemesius' *On the Nature of Man* and of several Galenic treatises (see Nemesius; Galen). In addition, Burgundio was probably responsible for the oldest Greek-Latin translations of Aristotle's *On Generation and Corruption* and *Nicomachean Ethics*, while the fourth book of the *Meteora* had been translated from Greek by Henricus Aristippus, archdeacon of Catania, before 1162. To Henricus we owe also a Latin version of Plato's dialogues *Phaedo* and *Meno*.

Many twelfth-century Greek-Latin translations that have come down to us are still anonymous. Sometimes it is possible, on the basis of certain similarities of style and terminology, to ascribe two or more of these versions to one and the same unknown scholar. Thus both the so-called 'Fragmentum Vaticanum' of the *Physics* and the 'Metaphysica Media' are probably the work of one person. Likewise, the anonymous Greek-Latin translation of Euclid's *Elements* seems to go back to the translator of the oldest Latin version of Ptolemy's *Almagest*, translated from Greek in Sicily about 1160 and so preceding Gerard of Cremona's Arabic-Latin rendering by more than ten years.

Around the turn of the century, Alfred of Sareshel, who may have learned Arabic in Spain, translated the pseudo-Aristotelian *De plantis* and an extract from Avicenna's *Meteora*. One of the most influential medieval translators was Michael Scot, active in the early thirteenth century, but the real extent of his work is not well known; attested are his versions of al-Bitruji's *On the Sphere* (made at Toledo with the help of 'Abuteus levita'), Aristotle's *De animalibus* in nineteen books (probably executed at the same place), and Avicenna's *De animalibus* (which must have been done in Italy, since it is dedicated to Emperor Frederick II). We cannot be as certain of his part in the translation of the huge Averroistic corpus. He certainly or probably translated into Latin Averroes' 'great' (that is, long) commentaries on the *Physics*, *On the Heavens*, *On the Soul* and *Metaphysics*, and these versions were the starting point for intensive study of those Aristotelian treatises (see Ibn Rushd). Averroes' 'middle' commentaries on the logical works were translated about the same time by William of Luna, while those on the *Nicomachean Ethics*, *Rhetoric* and *Poetics* were translated in this period by Hermann the German.

In the field of Greek-Latin translations, it is important to mention Robert Grosseteste for his rendering of the *Nicomachean Ethics* with commentaries by various authors, and of a fragment of the *De caelo* with Simplicius' commentary. In the second half of the thirteenth century, a number of pseudo-Aristotelian works were translated by Bartholomew of Messina at the court of Manfred, King of Sicily, while the corpus of Greek-Latin translations of Aristotle's genuine works was revised and completed by William of Moerbeke. This prolific translator, who worked in Greece and at the papal court, was responsible for the first complete Greek-Latin versions of the *On the Heavens*, *Meteora*, *De animalibus*, *Metaphysics*, *Politics* and *Poetics*. Moreover, he produced an impressive series of Latin versions of Greek commentaries on Aristotle, including *In Meteora* and *In de sensu* by Alexander of Aphrodisias, *In de interpretatione* by Ammonius, *In de anima* by Philoponus, *In categorias* and *In de caelo* by Simplicius, and *In de anima* by Themistius. In addition, William translated Proclus' *Elements of Theology* (see Proclus), *Tria opuscula*, *In Parmenidem* and *In Timaeum*, Alexander's *De fato*, several treatises of Archimedes and Eutocius, Heron's *Catoptrica*, Ptolemy's *De analemmate* and *Quadripartitum* and Galen's *De virtute alimentorum*. The Greek-Latin Galenic corpus was added to by Peter of Abano around the turn of the century and, particularly, by Nicholas of Reggio in the early fourteenth century.

Trinity

The doctrine of the Holy Trinity is a central and essential element of Christian theology. The part of the doctrine that is of special concern in the present entry may be stated in these words: the Father, the Son and the Holy Spirit are each God; they are distinct from one another; and yet (in the words of the Athanasian Creed), 'they are not three Gods, but there is one God'. This is not to be explained by saying that 'the Father', 'the Son' and 'the Holy Spirit' are three names that are applied to the one God in various circumstances; nor is it to be explained by saying that the Father, the Son, and the Holy Spirit are parts or aspects of God (like the leaves of a shamrock or the faces of a cube). In the words of St Augustine:

> *Thus there are the Father, the Son, and the Holy Spirit, and each is God and at the same time all are one God; and each of them is a full substance, and at the same time all are one substance. The Father is neither the Son nor the Holy Spirit; the Son is neither the Father nor the Holy Spirit; the Holy Spirit is neither the Father nor the Son. But the Father is the Father uniquely; the Son is the Son uniquely; and the Holy Spirit is the Holy Spirit uniquely.*
>
> *(De doctrina christiana I, 5, 5)*

The doctrine of the Trinity seems on the face of it to be logically incoherent. It seems to imply that identity is not transitive - for the Father is identical with God, the Son is identical with God, and the Father is not identical with the Son. There have been two recent attempts by philosophers to defend the logical coherency of the doctrine. Richard Swinburne has suggested that the Father, the Son and the Holy Spirit be thought of as numerically distinct Gods, and he has argued that, properly understood, this suggestion is consistent with historical orthodoxy. Peter Geach and various others have suggested that a coherent statement of the doctrine is possible on the assumption that identity is 'always relative to a sortal term'. Swinburne's formulation of the doctrine of the Trinity is certainly free from logical incoherency, but it is debatable whether it is consistent with historical orthodoxy. As to 'relative identity' formulations of the doctrine, not all philosophers would agree that the idea that identity is always relative to a sortal term is even intelligible.

1 The logical problem of the Trinity

The words 'the Trinity' are the English equivalent of the Latin word *Trinitas*, which was coined by the early Christian writer Tertullian. The word, which, etymologically, means something like 'the tripleness', is used to refer collectively to the Father, the Son and the Holy Spirit. (Tertullian also originated the use of the word 'person' (*persona*) as a common noun that applies to the Father, the Son and the Holy Spirit. Outside theology, the Latin word means a mask of the sort worn by characters in a classical drama, and, by extension, a *dramatis persona*, a character in a drama. What Tertullian's application of this word to the Father, the Son and the Holy Spirit was intended to suggest is disputed.) Theologians writing in Latin have generally said that, although God is a single *substantia*, there are in God three *personae*. Theologians writing in Greek have generally said that, although God is a single *ousia*, there are in God three *hypostases*. These two pairs of terms have caused some confusion, owing to the fact that *substantia* and *hypostasis* have the same literal or etymological meaning: 'that which stands under'.

The purpose of this entry is neither theological nor historical. Its purpose is rather to discuss the philosophical difficulties presented by the 'developed' doctrine (as it is to be found in the Athanasian Creed, of around AD 500). These difficulties are mainly logical. They are well stated in an anonymous seventeenth-century work that has been ascribed to the Socinian John Biddle:

> You may add yet more absurdly, that there are three persons who are *severally and each of them true God*, and yet there is but one God: this is *an Error* in counting or numbering; which, when stood in, is of all others the most brute and inexcusable, and not to discern it is not to be a Man.
>
> (quoted in Hodgson 1940)

The author of this passage is, essentially, charging that the doctrine of the Trinity implies a violation of the principle of the transitivity of identity, for it implies that the Father is identical with God, God is identical with the Son, and the Father is not identical with the Son. (For a full development of this charge, see Cartwright 1987.) The

central problem that faces the doctrine of the Trinity is this: how can the doctrine be stated in a way that is orthodox, clear and does not violate the principle of the transitivity of identity?

The doctrine of the Trinity is one of the Christian mysteries, which means that it cannot be seen to be true, or even to be possible, by the use of unaided human reason. This does not mean, however, that human beings, employing only their unaided reason, cannot usefully discuss the question whether the doctrine is formally self-contradictory. (If it could be demonstrated that the doctrine of the Trinity was formally self-contradictory, that would, of course, show that it was impossible; but the converse entailment does not hold.) The task undertaken in this entry does not, therefore, rest on a failure to appreciate the fact that the doctrine is held by those who accept it to be a mystery.

This entry will consider two recent attempts to avoid the conflict with Leibniz's Law that the doctrine of the Trinity seems to face (see Identity of indiscernibles §1). One proceeds by affirming that the Father, the Son and the Holy Spirit are numerically distinct from one another, and attempting to show that this thesis is consistent with historical orthodoxy. The other proceeds by denying the ultimate reality of numerical identity - and thus by denying that Leibniz's Law has anything to apply to. The first risks falling into tritheism, the heresy that there are three Gods. The second risks incoherence if not outright unintelligibility.

2 Swinburne's theory

Richard Swinburne (1988) has argued for a Trinitarian theology according to which the Father, the Son and the Holy Spirit are numerically distinct from one another and each of them is a God - each is a necessarily existent, omnipotent, omniscient, perfectly good being who is the creator of whatever world there may be, and who has each of these attributes essentially. Swinburne's theology, moreover, represents the Father as the creator of the Son. He does not, however, freely choose to create the Son, as he freely chooses to create a physical world. He is, rather, constrained by his own nature - by his perfect goodness - to create the Son (that is, he is constrained to create that very being, as opposed to being constrained to create some being or other who has certain properties that in actuality belong to the Son). 'There being a God and there being no physical world' and 'There being a God and there being a physical world that is "very good"' are morally or ethically indifferent states of affairs, and a God's perfect goodness does not, therefore, constrain him to prefer either to the other: which of these states of affairs obtains is a matter of the exercise of divine free will. But the two states of affairs 'There being only one God' and 'There being more than one God' are not morally or ethically indifferent; the second is better than the first, and the Father is, therefore, constrained by his own perfect goodness to prefer the latter. He therefore creates - eternally, of course: not at some point in time - the Son. Although Swinburne does not explicitly say this, it would appear that the individual essence of the Son must be supposed to include the property 'being created by the Father if any divine being is created by the Father'; if this were not the case, there would be no ontological ground for the fact that the Father creates the Son and not some other divine being. The Son is therefore a necessary being: he exists in all possible worlds, for the Father exists in all possible worlds, and, in every world in which he exists, he is constrained by his essential nature to create the Son. The necessity of the Father and the necessity of the Son may, in consequence, be contrasted by using a pair of phrases that Aquinas used in respect of a different kind of necessity (imperishability): the Father has his necessity of himself, but the Son receives his necessity from another.

The state of affairs 'There being more than one God' is better than the state of affairs 'There being only one God' because it is better that there should be a plurality of Gods who form a community of love than that there should be a solitary God. Swinburne argues, moreover, that it is better for a divine community of love to contain more than two Gods than to contain only two, for it is good for two beings to cooperate to benefit a third, and such cooperation could not exist within the divine nature if there were only two Gods. Hence, the Father and the Son are constrained by their moral perfection to cooperate to create a third God, the God called the Holy Spirit. There is, however, no good that requires the existence of more than three Gods, and the 'process' of the successive creation of Gods stops at three. (The ontological priority of the Father, Swinburne argues, gives him an authority over the Son and the Spirit, with the consequence that - of necessity - they conform their wills to his in matters about which a solitary God would have a free choice. The wills of the three Gods, therefore, can never be in conflict.)

Can Swinburne plausibly contend that his account of the Trinity is orthodox? There would seem to be two points on which Swinburne might be charged with unorthodoxy. There is, first, the fact that both the Creeds of the Church and every Trinitarian theologian whose writings have not been condemned have insisted that (as the Nicene Creed puts it) the Son is 'begotten, not made' (*genitus, non factus*). And, historical orthodoxy insists,

although the word ‘begotten’ is not used of the Holy Spirit, he too is ‘not made’. Second, one might well ask Swinburne why he should not be called a tritheist: after all, he says that there are three Gods, and tritheism is the thesis that there are three Gods. As to the first point, Swinburne contends that in the vocabulary of traditional theology, ‘create’ (*creare*) and ‘make’ (*facere*) have been used to express relations that God bears to finite, contingent creatures, and that traditional theologians would have objected to the words ‘*Pater filium creavit*’ only because they would have understood those words to imply that the Son was a finite, contingent being. If, however, the word ‘create’ is used in the very abstract sense of ‘eternally bring about the existence of’ - there being no implication that the being whose existence is brought about be contingent or finite - nothing contrary to historical orthodoxy is implied by ‘The Father created the Son’. On the second point, the charge of tritheism, Swinburne has chosen his words very carefully:

> A substance is not unnaturally understood as an individual thing which does not have parts capable of independent existence. Now the three persons are such that of logical necessity none can exist without the other…. They are therefore not unnaturally said to form one ‘first substance,’ and we may follow a natural tradition in calling that substance ‘God’.
>
> (1988: 236)

The sense of this passage seems to be this: the Father, the Son and the Holy Spirit are parts (albeit parts that are not ‘capable of independent existence’) of a composite being, and it is therefore natural to apply the name ‘God’ (derived from the general term ‘a God’, whose extension is the three divine parts of the composite being) to this composite being. If this is a correct interpretation of this passage, it seems unlikely that St Augustine or the framers of the Athanasian Creed would agree that Swinburne’s theory adequately captured the sense in which it is true of the Father, the Son and the Holy Spirit that ‘all are one God; and each of them is a full substance, and at the same time all are one substance’ (Augustine, *De doctrina christiana* I, 5, 5).

Whether or not Swinburne’s theory of the Trinity can plausibly be identified with the historical doctrine of the Trinity, it is clear that it faces none of the logical difficulties that the historical doctrine seems to face, for there are, according to Swinburne, three metaphysically simple beings to which the general term ‘a God’ applies, and one composite being to which the name ‘God’ applies. None of these four beings (of course) is numerically identical with any of the others, and each has - as their non-identity allows - properties that the others lack. Swinburne’s purpose was not simply to solve the logical problems that the historical doctrine seems to face, but to provide and argue for the truth of a comprehensive account of the ‘internal structure’ of the Trinity.

The other recent attempt to solve the logical problems raised by the doctrine of the Trinity is that and no more; the philosophers who have contributed to this attempt have been concerned only to show that the doctrine can be stated without internal logical contradiction, and they have said very little of an ontological nature about the Trinity.

3 Relative identity

The originator of this approach to the logical problems raised by the doctrine of the Trinity is Peter Geach (1977; Geach and Anscombe 1963), who has developed a theory according to which ‘identity is always relative to a sortal term’, which he has applied to the problems of counting and predication that confront the doctrine of the Trinity. Geach’s work has been continued by Martinich (1978) and van Inwagen (1988). The exposition that follows is a composite of things said by these three authors.

The ‘theory of the relativity of identity’ proceeds from the axiom that there is no such relation as numerical identity *simpliciter*: there is rather an indefinite number of relations expressed by phrases of the form ‘is the same *N* as’, where *N* represents the place of a count-noun. There are, for example, such relations as ‘is the same horse as’ and ‘is the same apple as’, but there is, strictly speaking, no such relation as ‘is the same as *simpliciter*’ or ‘is numerically identical with’. Identity *simpliciter* (expressed below by ‘Čequals;’) is defined by two characteristics: it is *universally reflexive* (everything bears identity *simpliciter* to itself) and it *forces absolute indiscernibility* (this characteristic is embodied in Leibniz’s Law or the principle of the indiscernibility of identicals: if $x = y$, then anything whatever that is true of *x* is also true of *y*). Relative-identity relations, however, are not in general universally reflexive. (Socrates is not the same horse as Socrates because Socrates is not the same horse as anything; that is to say, Socrates is not a horse.) Relative-identity relations, moreover, cannot be assumed to force

absolute indiscernibility - although any given such relation may have this feature. If it were assumed that every relative-identity relation forced absolute indiscernibility, then the logic of relative identities would simply be a fragment of the standard logic of identity *simpliciter*, and anything that could be said by using relative-identity predicates could be said equally well without them. (If every relative-identity relation forced absolute indiscernibility, then '*x* is the same *N* as *y*' could always be replaced by '*x* is an *N* and $x = y$'.)

The logic of relative identities is easily described. Its language is that of first-order predicate logic (without 'Čequals;' and the description operator, and without singular terms), its two-place predicates being partitioned into two classes (somehow visibly differentiated), the 'ordinary' two-place predicates, and the 'relative-identity' predicates. Its rules of inference are those of ordinary predicate logic, plus two rules that state, in effect, that relative-identity predicates express symmetrical and transitive relations. Relative-identity logic must do without anything corresponding to Leibniz's Law, for the reason outlined above. It must also do without singular terms. This is because a singular term is supposed to denote exactly one object (if it does not fail of denotation), and the concept of a singular term therefore involves the notion of identity *simpliciter*. (If *a* denotes *x* and also denotes *y*, it follows that $x = y$.) If, however, relative-identity logic is to have any power to represent ordinary, informal reasoning, its users must be able to employ some substitute for singular terms. This can be done through the use of an adaptation of Russell's Theory of Descriptions. For example, 'The present pope is bald' could be read as 'There is an *x* such that [*x* is at present a pope, and, for any *y* (if *y* is at present a pope, then *y* is the same man as *x*), and *x* is bald].' There is, of course, nothing special about the word 'man' that dictated its use in this sentence; we might as well have used 'person' or 'animal' or any of indefinitely many other count-nouns that would apply to anyone who was a pope. The sentence obtained by substituting 'person' in the above sentence is not equivalent in relative-identity logic to that sentence; to deduce either from the other, one would need a premise not endorsed by relative-identity logic. For example: 'For any *x* and for any *y*, if *x* is a man (that is, if *x* is the same man as something) and if *y* is a man, then *x* is the same person as *y* if and only if *x* is the same man as *y*.' No doubt most people would say that this proposition was *true*, but it is of the essence of the theory of the relativity of identities not to regard such propositions as truths of logic.

The customary term for 'what there is one of' in the Trinity is 'substance'. (But Geach and Martinich use 'God' for 'what there is one of' in the Trinity, and van Inwagen uses 'being'.) The customary terms for 'what there are three of' in the Trinity are 'person' and 'hypostasis'. (The relation between the meaning of 'person' in Trinitarian theology and 'person' in ordinary speech is a matter of dispute.)

All of the propositions of Trinitarian theology that raise logical problems can be represented using two relative-identity predicates ('is the same substance as' and 'is the same person as'), a predicate that expresses the divine nature ('is a God' or 'is divine'), and some predicates that express the relations that individuate the Father, the Son and the Holy Spirit. (The three persons or hypostases have traditionally been held to be individuated by the relations they bear to one another: the Father *begets* the Son; the Holy Spirit *proceeds from* the Father *and* - or *through* - the Son.) For example, the proposition that there are three divine persons can be expressed as 'There exist *x*, *y* and *z*, all of which are divine and are such that none of them is the same person as the others, and such that anything divine is the same person as one of them.' The proposition that there is one God (one divine substance) can be expressed as 'Something is divine and anything divine is the same substance as it.' These two sentences are consistent in relative-identity logic. The proposition that God is omnipotent can be expressed as 'Something is divine and anything divine is the same substance as it and it is omnipotent.' 'Reference' to the Father, the Son and the Holy Spirit can be accomplished by a device similar to the one that was used to 'refer' to God in the preceding sentence; in applying this device, use must be made of the predicates that express the relations that individuate the Father, the Son and the Spirit. Van Inwagen has shown (by constructing a model in which the interpretations of these sentences are true and in which 'is the same person as' and 'is the same substance as' express symmetrical and transitive relations) that the formal analogues of the whole set of logically problematic sentences endorsed by the doctrine of the Trinity are consistent in relative-identity logic. One striking consequence of this result is that the formal analogues of the sentences 'The Father is the same person as God', 'God is the same person as the Son' and 'The Father is not the same person as the Son' are consistent - and this despite the fact that 'is the same person as' expresses a transitive relation. (Needless to say, the formal sentences do not have the logical forms suggested by the English sentences they are held to translate.)

The main problem facing this account of the 'logic' of the Trinity would seem to be whether it is intelligible. Is it,

in the final analysis, intelligible to suppose, for some *x* and for some *y* - where *x* and *y* are both substances and both persons - that *x* is the same substance as *y*, but not the same person as *y*? Alleged non-theological cases in which *x* is the same *N* as *y*, but not the same *M* (the statue is the same lump of clay as the vase, but not the same artefact; Dr Jekyll and Mr Hyde were the same man but not the same person; James I of England and James VI of Scotland were the same man but not the same monarch) are all susceptible of lucid and plausible philosophical analyses that do not presuppose that 'identity is always relative to a sortal term'.

Troeltsch, Ernst Peter Wilhelm (1865-1923)

Ernst Troeltsch was a theologian, sociological historian, and philosopher of religion and history. He aimed to reconcile theology with modern scientific culture by grounding his philosophy of religion on historical analysis, and is regarded as the systematician of the 'history of religion school'. He is famous for his critical appraisal of the Protestant Reformation, which, he argued, had retarded the development of modern culture.

A native of Haunstetten, Bavaria, Troeltsch studied theology first at Erlangen, where the philosopher Gustav Class strove to reconcile idealism with empiricism and historicism, then at Berlin, where he attended Julius Kaftan's and Heinrich von Treitschke's lectures. Finally he went to Göttingen, where he became one of Albrecht Ritschl's (1822-89) last pupils. There he met progressive theologians who later formed the 'history of religion school', submitted his dissertation, and started work as an assistant lecturer. In 1894 he assumed the chair of systematic theology at Heidelberg, which he left in 1915 to take up a personal chair of philosophy at Berlin. The collapse of the German Empire lured him into politics and, as a committed democrat, he took an active yet unrewarding part in establishing the Weimar Republic. Politics clouded the close of his otherwise successful career.

As a theologian, Troeltsch searched for an auspicious compromise with modern secular culture. He was an apologist in disguise, who sought to moderate the shattering effect of modern science on orthodox belief. In a positivistic and historically conscious age, Christian theologians had to establish their discipline on a scientifically unassailable foundation. Neither supernatural revelation nor rational metaphysics but only history could fulfil such a function (Troeltsch 1902). A philosophy of religion drawn from analysis of the history and development of religious consciousness would, in Troeltsch's opinion, strengthen the standing of the science of religion among other sciences. In addition, it would assist the Christian strategy against materialism, naturalism, scepticism, aestheticism and pantheism. Besides, Troeltsch shared Wilhelm Herrmann's assumption that ethics provided the framework for the study of religion. An heir to both Schleiermacher's religious consciousness and Hegel's concept of development, Troeltsch unfolded an idealism of historical development, which aimed at bridging the gulf between 'scientific' (historical) and 'dogmatic' (ecclesiastical) theology. He therefore ascribed to theology a threefold task: the justification of the supremacy of Christianity on a historical and comparative religion basis; the specification of the essence of Christianity; the exposition of the Christian understanding of God, the world, the soul and redemption.

As a historian, Troeltsch interpreted Protestant and Roman Catholic Christianity, as well as contemporary intellectual culture, from a philosophical-sociological perspective (Troeltsch 1906a, 1915). He emphasized the cultural value of religion and derived most standards of truth and value from an analysis of history. In Dilthey's wake, he also reflected on the relation of historiography and relativism (Troeltsch 1922). As a philosopher, Troeltsch upheld a post-Kantian, eclectic idealism. Initially close to Hermann Lotze and Wilhelm Dilthey, he later shifted to the School of Baden (Windelband, Rickert). However, he opposed the neo-Kantian distinction between knowledge and faith then current, and refused to ground religious belief in value-judgments alone. In *Das Historische in Kants Religionsphilosophie* (The Historical in Kant's Philosophy of Religion, 1904), Troeltsch strove to restore a more authentic Kant, in whom he found evidences of the beginning of a modern historical consciousness.

Die Bedeutung des Protestantismus für die Entstehung der modernen Welt (*Protestantism and Progress*, 1906b) argues that early Protestantism marked a retreat to medieval theocratic civilization. By holding to the principle of authority and enforcing inward asceticism, the Protestant Reformation merely modified medieval Catholicism and thereby delayed the development of modern culture. It was the Enlightenment that fulfilled the Renaissance and produced the modern world. With regard to sociology, Troeltsch closely followed Max Weber, though he disagreed with him on some issues. His masterpiece, *Die Soziallehren der christlichen Kirchen* (*The Social Teaching of the Christian Churches*, 1912), considers whether the development of religious beliefs and movements was conditioned by external factors and whether, in turn, religion has influenced society and culture. From a detailed study of Christian social history, Troeltsch derived three types of sociological self-formation of the Christian idea: the Church, the sect and the mystic. It was Troeltsch's conclusion that the permanent quest for, and opposition to, a cultural compromise wove the fabric of the Christian ethos.

Trotsky, Leon (1879-1940)

Trotsky's chief claim to attention is as the leader of the Russian Revolution who opposed the consolidation of the Stalin regime in the Soviet Union and sought to dissociate the classical Marxist tradition from that regime and its official ideology. In doing so, however, he developed a version of Marxism which sought to give proper place to the 'subjective factor' in history, and at the same time to integrate Marx's social theory into a broader, dialectical theory of nature.

Trotsky's life belongs chiefly to the principal drama of the twentieth century - the Russian Revolution of October 1917 and the emergence, in its aftermath, of the Stalinist regime which survived until the collapse of the Soviet Union in 1991. Born in Yankova, Lev Davidovich Bronstein assumed the name Leon Trotsky while escaping exile in Siberia in 1902. A revolutionary activist from his teens, he presided over the St Petersburg Soviet of Workers' Deputies during the 1905 Revolution, and held the same position when, as a leader of the Bolshevik Party, he helped organize the uprising of October 1917. As War Commissar, Trotsky played a pivotal role in securing a Bolshevik victory in the post-revolutionary Civil War. Defeated in the factional struggles which led to the dominance of Josef Stalin in Party and state, he was exiled in 1929. Trotsky spent his remaining years desperately seeking to rally socialist opposition to the Stalin regime. Isolated and persecuted, he was murdered by a Soviet agent.

Trotsky's voluminous writings reflect this life. They represent an attempt to preserve and to extend the classical Marxist tradition in opposition to Stalinism and its official ideology of Marxism-Leninism. This stance distinguishes Trotsky from Western Marxists such as Adorno, Marcuse and other members of the Frankfurt School, who kept their distance equally from the Soviet regime and from classical Marxism, which they tended to regard as excessively and reductively materialist (see Frankfurt School; Critical theory).

Trotsky was, by contrast, an unapologetically orthodox Marxist. Thus he sought to provide an explanation of Stalinism which took as its starting point the economic circumstances of the Bolshevik regime after 1917. It was the isolation of the Revolution and the consequent prevalence of scarcity in a backward, predominantly peasant country that accounted for the rise of Stalin and the *nomenklatura*. At the same time, however, he vehemently denied that Marxism was a version of economic determinism. His theory of permanent revolution, first developed after the 1905 Revolution, sought to show how processes of 'uneven and combined development' on a world scale made possible socialist revolutions even in underdeveloped countries such as Tsarist Russia. Similarly, Trotsky's political and historical writings constantly stress that the outcomes of social and political crises are not predetermined by the economic contradictions that cause them, but depend on the 'subjective factor' - human agency in the shape of social classes, political organizations and even individual leaders.

A similar combination of orthodoxy and flexibility characterizes Trotsky's strictly philosophical writings, which are devoted to a defence of the proposition that Marxism possesses a dialectical method which sets it apart from other social theories. Marx inherited from Hegel the idea that contradictions exist in reality and developed it into a theory of social contradictions - for example, the structural conflict between capitalist relations of production and the development of the productive forces. Engels then extended this, most notably in *Dialectics of Nature* (1925), into a general theory of nature, in which certain dialectical laws govern both physical and social worlds.

'Dialectical materialism' thus understood became a basic element of Marxist orthodoxy (see Dialectical materialism). During the 1930s, however, some of Trotsky's US followers, influenced by pragmatism, sought to separate Marxist social theory from this broader metaphysical doctrine. Trotsky responded vigorously, arguing that abandonment of the dialectic would lead sooner or later to the rejection of Marxism itself. The dialectical method was indispensable for scientific inquiry. Following Hegel, Trotsky argued that formal logic is unable to comprehend any process of change:

> It wishes to content itself with motionless imprints of a reality which consists of eternal motion. Dialectical thinking gives to concepts, by means of closer approximations, corrections, concretizations, a richness of content and flexibility; I would even say a succulence which to a certain extent brings them close to living phenomena.

([1942] 1973: 50)

The more scientific discoveries reveal nature itself to be undergoing processes of historical transformation, the more important the dialectical method becomes: thus Darwin was an ‘unconscious dialectician’ ([1942] 1973: 51-4). But this line of argument poses the following dilemma. If Darwin could get as far as he did ‘unconsciously’, what need of a ‘conscious’ dialectic? If, on the other hand, research is held to depend on dialectical thinking, does this not license the kind of ideological terror suffered by Soviet biologists during the Lysenko era?

Trotsky, however, loosened Engels’ conception of universal ‘laws of the dialectic’. Only ‘the conversion of quantity into quality’ - the concept of qualitative transformation - is ‘the fundamental law of dialectics’ because ‘the entire universe’ is ‘a product of formation and transformation’ (1986: 88-9). One such ‘transition from quantity to quality’ is ‘"the autonomy" of psychological phenomena’: ‘the psyche, arising from matter, is "freed" from the determinism of matter, so that it can - by its own laws - influence matter’. Trotsky compared this to the interaction between base and superstructure - ‘politics grows out of economics in order for it in turn to influence the base’ - but admitted that the relationship between mind and body is ‘incomparably more puzzling’ (1986: 106-7). Nature is thus conceived as stratified - divided into distinct domains each governed by its own laws - yet forming an integrated and historically evolving totality. The dialectic is not a substitute for empirical research into these different domains, but ‘it gives investigative thought elasticity, helps it to cope with ossified prejudices, arms it with invaluable analogies, and educates it in a spirit of daring, grounded in circumspection’ (1986: 92). Although even many Marxists regard the idea of a dialectic of nature as an embarrassment, Trotsky would no doubt argue that it has been vindicated now that cosmologists tell us of a universe formed through a series of phase transitions producing radical changes in physical structures.

Trust

Most people writing on trust accept the following claims: trust involves risk; trusters do not constantly monitor those they trust; trust enhances the effectiveness of agency; and trust and distrust are self-confirming. Three further claims are widely accepted: trust and distrust are contraries but not contradictories; trust cannot be willed; and trust has noninstrumental value. Accounts of trust divide into three families: risk-assessment accounts, which are indifferent to the reasons why one trusts; will-based accounts, which stress the importance of the motives of those who are trusted; and affective attitude accounts, which claim that trust is a feeling as well as a judgment and a disposition to act. One of the central questions concerns when trust is justified, and, in particular, whether justified trusting can outstrip evidence for the belief that the person trusted is trustworthy. If trust can leap ahead of evidence of trustworthiness, then trust poses a problem for evidentialism, or the view that one should never believe anything without sufficient evidence. Further central questions include whether trusting is a virtue and trustworthiness morally required, while a final set of questions concerns the role of trust in politics and the connection between interpersonal trust and trust in institutions.

1 Common observations about trust

Trust is part of love and friendship, and vital for any cooperative task. Trust's pervasiveness can render it almost invisible; we notice how much we trust only when trust has been betrayed.

Any account of trust should aim to be compatible with and seek to explain a number of commonly accepted observations. There is a core of four such observations which are generally accepted by people writing about trust and a further three which, while not universally accepted, are frequently noted. The four core observations about trust are as follows.

(1) Trust involves risk. A person who trusts another is willing both to run the risk of letting them near things that they care about, and to rely on their words and promised actions. When trust is betrayed the truster is usually left worse off than had they refrained from trusting. (2) Those who trust are willing to forgo an immediate accounting of how or even whether the one trusted has responded to trust with trustworthiness, and to allow the one trusted some discretion as to how to fulfil that trust. While contractual relations might involve a degree of trust, noncontractual trust relations are distinguished from contractual arrangements by their relative open-endedness. When there is trust, there is no need to specify exactly what must be done to fulfil it. The flexibility of trust relations in part explains trust's usefulness: contingency and ignorance often make us unable to specify what we are counting on the other to do; trust removes the need to do so. (3) Trust enhances the effectiveness of agency: it enables us to attempt cooperative tasks that could not rationally be attempted without trust, and, as Luhmann (1973) points out, it lets us inhabit a simpler and less threatening world, a world in which we need not plan for every contingency. (4) Trust and distrust are self-confirming, distrust even more strongly so than trust. When there is distrust, cooperative relations will be minimized and there will be little chance of getting evidence that the person is after all trustworthy. Trust and distrust also influence how we interpret the actions and behaviour of others: when there is room for a more or less favourable interpretation, we will adopt the interpretation which most fits with our view of their trustworthiness. In addition, sometimes displaying trust or distrust itself affects the behaviour of the person in question and tends to make them either trustworthy or untrustworthy.

Three additional claims enjoy wide agreement. (5) Trust and distrust are contraries but not contradictories. Just because one does not trust, it does not follow that one thereby distrusts, for there can be a neutral stance of neither trusting nor distrusting. (6) Trust cannot be willed. One cannot will oneself to trust in the acknowledged presence of substantial reasons to distrust, though one may be able to make oneself act as if one trusted. (7) The value of trust is not exhausted by its instrumental role in making possible cooperative relations. Trust, when well placed, is valuable in itself and is a constitutive part of other things valuable in themselves, such as love and friendship (see Friendship §1).

2 Accounts of trust

Accounts of trust divide into three families, depending on the degrees to which they distinguish trust from reliance, and to which they emphasize affect or feeling.

The first family of accounts view trust as a form of risk assessment (see Risk assessment). Such accounts tend to begin by considering trust in institutions and then extend the results of that reflection to cover interpersonal trust. Gambetta offers the following definition of trust:

> trust (or, symmetrically, distrust) is a certain level of subjective probability with which an agent assesses that another agent or group of agents will perform a particular action, both *before* he can monitor such action (or independently of his capacity ever to be able to monitor it) *and* in a context in which it affects *his own* action.
> (1988: 217; original emphasis)

The definition emphasizes the way trusting makes one vulnerable, but it does not distinguish among the reasons why one might assign a sufficiently high degree of probability to agents' performing an action. One might think agents will perform that action out of fear or stupidity, or because it coincides with their own self-interest, or because they have, and wish to display, goodwill towards those who are counting on them. Gambetta includes all these alike in his definition. Proponents of such accounts are thus unlikely to accept that trust is anything other than instrumentally good, for if trust can rest on any assessment of motivation it is hard to see how it could be valuable in itself. Several writers hold that accounts which ignore motivation confuse trust with mere reliance.

Trust is distinguished from reliance in two ways. One can rely on something, or someone, simply because one has no choice but to do so: the bridge, rickety and unsafe though it might be, is the only way to escape the oncoming fire and so one is forced to rely on it and hope for the best. When one trusts, in contrast, one has the confident expectation that the one trusted will respond favourably. According to Thomas Hobbes, '[t]rust is a passion proceeding from the belief of him whom we expect or hope for good, so free from doubt that upon the same we pursue no other way' (1650).

Trust is thus distinguished from hope by confidence of expectations. But confident expectations can be grounded in all manner of psychological features. Most who clearly distinguish trust from reliance suggest that the difference is that in trust one relies on goodwill rather than on some other aspect of a person's psychology. Thus, the second family of accounts of trust, will-based accounts, tend to begin by considering interpersonal trust. Annette Baier's article, 'Trust and Anti-trust', offers an entrusting model. On this model, trusting is a three-place relation: A trusts B with valued thing C (1986: 236); and trusting is distinguished from mere reliance in so far as trust is always reliance on the goodwill (and competence) of another. We value another's goodwill towards us in itself, not merely because of its usefulness; therefore, on will-based accounts, the value of well-placed trust is not exclusively instrumental.

The first two families of accounts of trust take trust to involve both cognitive and conative aspects, both judgments about the likely actions of another and readiness to undertake risky actions on the basis of those judgments. The third family of accounts, affective attitude accounts, adds an affective aspect: trust is a feeling as well as a judgment and a disposition to act. '[Trust] has a special "feel", most easily acknowledged when it is missed, say, when one moves from a friendly, "safe" neighbourhood to a tense, insecure one' (Baier 1992: 112-3).

3 When trust is justified

If our trust in strangers can be justified, then it seems that we sometimes trust without good evidence for the belief that the one trusted is trustworthy. Thus trust, like faith, might seem to conflict with evidentialism, or the view that we should never believe anything without sufficient evidence (see Faith). In response, we might claim that in certain social climates we have sufficient evidence that strangers will be trustworthy and that outside such climates our trust in strangers is unjustified. In this way we reconcile trust with evidentialism by requiring trust to meet the normal justification standards for belief. Alternatively, we might, following some writers on faith, reject evidentialism and claim that trust does not require the same evidence as other beliefs but can still be justified. Finally, we might stress the affective aspect of trust and claim that since evidentialism governs the adoption of beliefs and not the adoption of affective attitudes, trust falls outside the scope of the evidentialist requirement.

It might be thought that trust should be our default stance: if we distrust without solid evidence of untrustworthiness our willingness to assume ill will or unreliability shows a lack of respect for the person distrusted (see Respect for persons). At least initially, everyone should be given the benefit of the doubt. On this view, willingness to trust is a virtue (see Virtues and vices §§2-3). Similarly, it might be thought that we are

required to respond to trusting with trustworthiness, and so when trust is betrayed the moral fault always lies with the one who responded to trust with untrustworthiness. Both of these claims ignore how trust and trustworthiness can be used to foster exploitation, to hide abuse and to promote cooperation in the service of unworthy ends. In this respect, trust and trustworthiness are like loyalty. Loyalty can promote bad causes as well as good ones. Sometimes, one is required to respond to trust with selective untrustworthiness, and to demands for loyalty with judicious disloyalty. Just because well-placed trust has noninstrumental value, it need not follow that poorly placed trust has such value.

What conditions are likely to give rise to trust and how is trust to be maintained and extended? Good's contribution to the Gambetta volume shows that some insight into these questions can be gained from game theory and from laboratory studies of cooperation (see Decision and game theory §§3, 6, 8). Trustworthy behaviour is more likely to be shown by those who are engaged in ongoing cooperative exchanges since, by being untrustworthy, they risk losing the benefits of all future cooperative exchanges. Likewise, communication facilitates trust since the more we know about persons, the more certain we can be about how they will act. Trust is more easily extended in incremental steps because we do not deliberate extensively about small extensions to previous policy; further, trust is more easily developed through small initial risks. These observations suggest strategies for those who would initiate and develop trusting relations. Baier (1992) offers a sensitive discussion of the functional virtues needed to maintain trust. Chief among them are tact and willingness to forgive breaches in trust, though judgment is indispensable in working out which breaches should be forgiven, and which not.

4 Trust and social and political institutions

Social and political institutions (such as licensing boards, marketplaces and schools) can make possible and strengthen interpersonal trust, by removing incentives to untrustworthiness and so creating a confluence of motives for trustworthiness, by helping to create stable expectations and by providing a framework for understanding communication and interpreting behaviour.

If social and political institutions can underwrite interpersonal trust, could it be possible to replace interpersonal trust with trust in well-designed institutions? Trusting in institutions rather than in individuals would eliminate the need for information about particular persons filling institutional roles. We could count on whoever happens to fill a well-designed social role. In large impersonal societies, where we must frequently interact with persons unknown to us, the advantages of shifting from interpersonal to institutional trust are obvious. The contrast between institutional and interpersonal trust is not hard and fast, and a particular instance of trust, say trust in one's physician, could involve elements of both. That the two sorts of trust can overlap suggests we need not think it possible to replace interpersonal trust with institutional trust to think it worth heading in such a direction.

One reason for being suspicious of the claim that we should trust in institutions is the concern that doing so requires that we forswear vigilance and forgo checking. Consider the claim, advanced by John Locke (1690), that the relation between citizens and government is one of trust. If trust is generally appropriate towards parents and always appropriate towards God, it might be thought just plain foolish towards governments. This objection is based, however, on a misunderstanding of the way theorists have thought that the notion of trust enters into the relation between citizens and government. According to Locke, citizens entrust the government with coercive power to act on their behalf for their benefit and for the protection of their rights. When governments fail to fulfil their trust, they lose legitimate authority (see Locke, J. §10). The people also retain the power to judge when a breach of trust has occurred:

> for who shall be *Judge* whether his Trustee or Deputy acts well, and according to the Trust reposed in him, but he who deputes him, and must, by having deputed him, have still a Power to discard him, when he fails in his Trust?
>
> (1690: 445; original emphasis)

That the relation between government and governed is one of trust is thus compatible with holding the government accountable, provided that we understand the relation in question to be one of entrusting. However, for societies to flourish they need political institutions that merit trust and allow citizens to be confident that power is safely entrusted to them.

How significant one finds trust to be in public life will depend in part on the account of trust that one adopts. Thus, while risk-assessment accounts encounter problems thinking about interpersonal trust, will-based accounts are less readily generalized from interpersonal relations to social and political institutions.

Truth, coherence theory of

The term 'coherence' in the phrase 'coherence theory of truth' has never been very precisely defined. The most we can say by way of a general definition is that a set of two or more beliefs are said to cohere if they 'fit' together or 'agree' with one another. Typically, then, a coherence theory of truth would claim that the beliefs of a given individual are true to the extent that the set of all their beliefs is coherent. Such theories, thus, make truth a matter of a truth bearer's relations to other truth bearers rather than its relations to reality. This latter implication is the chief hindrance to plausibility faced by coherence theories, and most coherence theorists try to escape the problem by denying that there is any extra-mental reality.

1 Essential elements of coherence theories

John Locke voiced what might be the earliest statement of a coherence theory of truth when he said in *An Essay Concerning Human Understanding* that ideas are true if they agree with each other. But a few pages later he reverted to a correspondence theory by declaring that there were 'chimerical' truths and real truths, and what distinguishes the latter from the former is that real truths agree with reality. When the character Philonous, representing George Berkeley in the latter's *Three Dialogues*, is asked how his idealist doctrine can distinguish fact from fiction, reality from illusion, and waking life from dreaming, he replies that fictional ideas, illusions, and dreams are known to be such because they are disconnected from the great mass of the rest of our ideas. This can be taken as an endorsement of what would today be called a coherence theory of truth. Moreover, coherence theories were in their golden age during the nineteenth century, the heyday of ontological idealism in Western philosophy. It is not surprising that coherence theories should cohabit with anti-realist ontology. If reality itself is just a system of mental entities - thoughts - then not even the true thoughts can correspond to some *other* reality, since there is no other. So, it would be natural to suppose that the truth of a true thought must consist in its relations to other thoughts (see Truth, correspondence theory of §2).

Nineteenth-century coherence theories provided a more detailed definition of coherence: a set of beliefs coheres if and only if each member of the set is consistent with any subset of the others, and if each is implied (inductively, if not deductively) by all of the others taken as premises or, according to some coherence theories, each is implied by each of the others individually.

Unfortunately, the distinction between theories of justification and theories of truth was not deployed in the nineteenth century. As a result, there are few individuals to whom one can unhesitatingly attribute a coherence theory of truth, distinct from a coherence theory of justification. One to whom we can make such an attribution is Brand Blanshard: ' coherence is the sole criterion of truth. We have now to face the question whether it also gives us the nature of truth… one may reject coherence as the definition of truth while accepting it as the test' (Blanshard 1941: 260). *Pure* truth, he says, is a fully coherent set of beliefs, and ' fully coherent knowledge would be knowledge which in every judgment entailed, and was entailed by, the rest of the system'. But even this understates the entailment relations between the members of the system: ' every proposition would be entailed by the others jointly and even singly'. Since an inconsistent subset of beliefs would trivially entail anything and everything, and since presumably Blanshard does not want that kind of entailment to be a truth-making relation, there is an implied condition of consistency on any system of beliefs before it will count as true. However, Blanshard does not want to say that two such systems, each coherent within itself but inconsistent with the other, are *both* true. A true system of beliefs would be one 'in which everything real and possible is coherently included'. So, a purely true system would be one that gives us a complete picture of the world. This theory can be expressed in the following formula:

> For each belief, *b*, *b* is purely true if and only if *b* is a member of a consistent set of beliefs that among them give a complete picture of the world and each of which entails each of the others.

But pure truth has never been attained, so Blanshard, typically for a coherence theorist, proposes that truth comes in degrees: ' A given judgment is true in the *degree* to which its content could maintain itself in the light of a completed system of knowledge, false in the *degree* to which its appearance there would require transformation' (Blanshard 1941: 304). This is captured in the formula:

For each belief, *b*, *b* is true to degree *n* if and only if *n* per cent of the content of *b* would be present in a purely true system of beliefs.

2 Objections to coherence theories

The most common objection to coherence theories is that the conditions they place on truth are too weak. Traditionally, this objection is expressed with the quip that on a coherence theory a well-written novel would be true, literally not figuratively. Taken at face value, such an objection is only telling against those theories which require mere mutual consistency for coherence. But there are no such coherence theories. Blanshard's, as we have seen, requires mutual entailment among the beliefs in a set if the set is to count as coherent. Nevertheless, it is certainly possible to construct two sets of consistent, mutually entailing propositions which contradict each other and which, thus, cannot both be true. Blanshard of course, following Bradley (1914), tries to eliminate this possibility by insisting that final truth is found only in a set which is not only coherent but also *complete*. Yet even this might not be a strong enough condition on truth. Could there not be two complete pictures of the universe, inconsistent with each other, but each internally coherent? Since there is not even one such complete picture, an answer to that question must remain uncertain; but it is worth noting that there are large domains of phenomena for which humankind possesses two (or more) competing theories, each of which seems to have approximately equal degrees of internal coherence. There are for example the geometries of Euclid and Riemann; and one thinks also of Western medicine, on the one hand, and the traditional medicine of China, on the other.

Since the concepts of entailment and consistency are usually defined in terms of truth, a theory which, like coherence theories, defines the latter concept in terms of entailment or consistency is uninformatively circular. One might try to eliminate the circularity by defining entailment and consistency in terms of a certain set of rules of derivation; for example '*p* entails *q* if and only if *q* can be derived from *p* via one or more of the rules in *R*', where *R* is a set of rules of inference whose members refer only to the syntactic structure of propositions, not to their truth values. One such rule might be 'from propositions of the form *p* and "if *p*, then *q*", one may derive the proposition *q*'. But suppose *R* contains 'from a proposition *p*, one may derive the proposition "not-*p*"'. Then no one would take seriously a theory claiming that a set of propositions that are mutually 'entailing' via such a set of rules is, for that reason, true. Hence, defining entailment and consistency proof-theoretically requires that the set of rules in question be restricted to those which are *truth*-preserving; and so the circularity problem arises again.

Defining the truth-value of a truth bearer in terms of its relations with other truth bearers instead of its relations with the world is initially considered implausible by most, because doing so seems to make it logically possible for 'Kendall is red-headed' to be true even if she is not in fact red-headed, and for 'Emory is handsome' to be false even if he is, in fact, handsome. The only way to make such situations impossible is to embrace an anti-realist notion of what it is to be a fact. For example, if we define a fact to be an idea in the mind of God and declare that God's ideas are a complete and perfectly coherent set, then facts and truths are not disjoint. But since the plausibility of the coherence theory depends on an anti-realist ontology, the difficulties facing such ontologies become difficulties for the coherence theory (see Idealism; Realism and antirealism).

3 Scepticism and coherence theories

Given the difficulties facing coherence theories of truth, one might wonder why some have found them attractive. There are remarkably few positive arguments for such theories in the literature, and those which can be found are nearly all variations on what might be called the argument from scepticism - that it is very hard (some would say it is impossible) ever to be justified in believing that this or that is a mind-independent fact. Our subconscious minds so thoroughly filter and modify observational input that what we take to be facts have no resemblance to any mind-independent facts. So, if we make the existence of a mind-independent fact a necessary condition for the truth of a belief (or sentence, or whatever) we would never be justified in thinking that *any* belief is true. Thus, such a theory of truth would entail scepticism. Given that scepticism is wrong, so too must be any such theory of truth.

But begging the question is no more respectable when directed against scepticism than when directed against any other philosophical proposal. A sceptical thesis such as 'No belief is justified as true' (which does not say 'I am justified in believing that no belief is justified as true') is not self-contradictory and thus might well be correct. That pill will be less bitter if we remember that it need not imply that no belief is any more rational than any other;

for the rationality of beliefs could be defined in terms of their possession of values, such as explanatory power, *other than* the value of being justified as true.

A second problem with the argument from scepticism for coherence theories of truth is that the latter theories do not really solve the problem of scepticism anyway. Coherence theorists of truth, in effect if not in intention, try to deal with scepticism by redefining truth so as to make it more attainable. They define it in such a way that it becomes easy to have beliefs justified as probably true. But no satisfying rebuttal to scepticism can come from this strategy, for the problem of scepticism is the concern that our beliefs may not be justified as accurate reflections of a mind-independent world. The manoeuvre under consideration tells us in the large print that we have adequate justification for most of our beliefs about the world; but, simultaneously, the small print tells us that this 'world' we believe in consists of mental constructs and may not even vaguely resemble the mind-independent world. Of course, a coherence theorist of truth believes we are mistaken in thinking there is any mind-independent world in the first place. But to say this is to surrender to scepticism, not to refute it. Davidson makes the same point thus: '[Such theories] are sceptical in the way idealism or phenomenalism are sceptical; they are sceptical not because they make reality unknowable, but because they reduce reality to so much less than we believe there is' (Davidson 1990: 298).

Truth, correspondence theory of

The two oldest theories of truth in Western philosophy, those of Plato and Aristotle, are both correspondence theories. And if the non-philosopher can be said to subscribe to a theory of truth, it would most likely be to a correspondence theory; so called because such theories are often summed up with the slogans 'truth is correspondence with the facts' or 'truth is agreement with reality'. Aristotle puts it thus: 'to say that [either] that which is is not *or that which is not* is, *is a falsehood; and to say that that which is is and that which is not is not, is true'. In epistemology, such theories offer an analysis of that at which, supposedly, investigation aims: truth. But correspondence theories are also now thought to play important roles in philosophical semantics and in the physicalist programme, which is the task of reducing all non-physical concepts to the concepts of logic, mathematics, and physics.*

1 Two kinds of correspondence theory

Correspondence theories come in two varieties - correspondence as correlation, and correspondence as congruence. The former variety asserts that every truth bearer (proposition, sentence, belief, and so on) is correlated to a possible fact. If the possible fact to which a given truth bearer is correlated actually obtains, the truth bearer is true; otherwise it is false. What the correspondence-as-correlation theory does not claim is that the truth bearer depicts, or is structurally isomorphic with, the possible fact to which it is correlated. Rather, a truth bearer as a whole is correlated to a possible fact as a whole. A correspondence-as-congruence theory does claim that truth bearers and the possible facts to which they correspond have parallel structures. Representing this second school is Bertrand Russell, who affirms that Othello's belief that Desdemona loves Cassio is a complex relation between Othello (the subject), Desdemona (an object-term), Cassio (another object-term) and loving (the object-relation) (Russell 1912). Truth requires a congruence between this four-term relation and a second, three-term relation called 'a fact' which has Desdemona, loving, and Cassio (in that order) as its terms. If such a three-term relation exists in reality, then Othello's belief is true. If there is no such fact, the belief is false (see Russell, B. §10).

J.L. Austin has offered a correspondence-as-correlation theory. Truth is considered as a single, four-term relation between a statement, a sentence, a state of affairs (that is, a possible fact), and a *type* of state of affairs. For Austin, a statement is the information conveyed by a declarative sentence. So a sentence is the medium in which a statement is made. And the meaning of statements is a matter of two kinds of conventions that have evolved in our language. First, there are descriptive conventions correlating *sentences* with types of states of affairs. Second, there are demonstrative conventions correlating *statements* to particular states of affairs. Thus, ' A statement is said to be true when the historic [that is, particular] state of affairs to which it is correlated by the demonstrative conventions (the one to which it "refers") is of a type which the sentence used in making it is correlated by the descriptive conventions' (Austin [1950] 1970: 121-2). Hence, 'there is no need whatsoever for the words used in making a true statement to "mirror" in any way, however indirect, any feature whatsoever of the situation or event'. The correspondence between the truth bearer and the world is '*absolutely and purely* conventional'. For example, 'the cat is on the mat' would in an ordinary context refer to the present state of affairs in which speaker and hearer find themselves, along with a cat and a nearby mat. Therefore, if a cat is on a mat in the state of affairs in which the speaker is located, the statement is true because the present state of affairs is of just the type described by the sentence.

In favour of the correspondence-as-correlation view is the fact that some sentences (for example, the Latin word 'sum', which translates as 'I am') are atomic meaning units which have no internal semantic structure and thus could correlate with possible facts only whole-for-whole.

2 The common essence of correspondence theories

If we strip out of Russell's theory of truth the assumption that beliefs are four-termed relations, and strip out of Austin's theory his assumptions about meaning being a matter of conventions, we can then encapsulate the two stripped-down theories of truth in these two formulas:

Russell: A belief is true if and only if it is a belief that an object x bears relation R to another object y, and x does

bear relation *R* to *y*.

Austin: A statement is true if and only if it expresses a state of affairs, and that state of affairs obtains.

If we abstract the common elements of these two theories, we get the following thesis which can be taken as expressing the common denominator of all correspondence theories of truth:

Correspondence: A truth bearer is true if and only if it corresponds to a state of affairs and that state of affairs obtains.

But it must be emphasized that the 'corresponds to' in this thesis does not express some particular relation. Rather it should be thought of as a placeholder which any given correspondence theory would replace with some particular and familiar relation. Which relation a particular correspondence theorist would cite will vary, depending on their choice of truth bearer. For beliefs, the relation would be 'is a belief that'. For linguistic entities such as sentences, 'says that' or 'means that' or 'expresses' would be more appropriate choices. If a proposition is the bearer in question, then the appropriate relation would depend on how one defines propositions. (The differences between the formula expressing Russell's theory and the schema are attributable to Russell's conviction that the belief must be isomorphic to the corresponding fact.)

Note that the 'obtains' in the correspondence schema does not require that the state of affairs should obtain mind-independently. It is perfectly possible to hold that truth consists in correspondence with facts and to hold also that facts are mind-dependent entities. McTaggart (1921) endorsed such a correspondence theory, and Kant (1781) and Wilfred Sellars (1963) can be read this way too (see Kant, I.; McTaggart, J.M.E.; Sellars, W.). Thus, while most correspondence theorists have been ontological realists, the common belief that a correspondence theory is committed to realism is erroneous.

3 Objections to correspondence theories

Traditionally, three kinds of criticisms have been levelled at correspondence theories. The first concerns whatever it is the theory identifies as the truth bearer (beliefs, propositions, statements and so on): some allege that such things cannot, for various reasons, be truth bearers. Second, some allege, about whatever (facts, situations, states of affairs and so on) is identified by the theory as the correspondent of the truth bearer, that such things cannot, for various reasons, serve as the correspondents. Third, there are objections to the alleged relation between truth bearers and reality on the grounds that there is no such relation or that its nature has not been clearly explained by the theory.

The first sort of issue arises with any kind of truth theory, so nothing more will be said of it here. The third sort of objection is rarely legitimate because it aims at the sort of slogans with which correspondence theorists sum up their theories (for example, 'truth is a correspondence with the facts') and is thus irrelevant to the theories themselves, such as that of Russell and Austin, in which no such special relation makes any appearance. A closely related objection is that correspondence theories use concepts like 'belief' or 'means that' which themselves have no undisputed philosophical analysis. But such an accusation is of dubious significance precisely because it is difficult to imagine any philosophical theory against which the same objection could not be made: philosophically important topics tend to link with one another, so such an objection implicitly assumes that a theory does not solve any problem unless it solves every problem.

A correspondence theorist's description of the connection between truth bearers and facts is largely dictated by the choice of truth bearer anyway. And the latter choice, in turn, is dictated by the needs of the broader philosophical programme which has 'placed an order' for a theory of truth. Traditional epistemology is concerned with the comparative evaluation of competing theories about how our beliefs can be justified as likely to be true. But such evaluations would be impossible without first having a notion of what truth, specifically, what true *belief*, is. On the other hand, the Davidson programme aims to put a theory of truth to work in semantics and, thus, requires a theory of true *sentences* (see Davidson, D. §4).

Many have rejected the very notion of a fact as some non-linguistic entity existing in the world; facts are really just reifications of true sentences. The evidence for the claim that 'fact' is just another name for 'true sentence' is supposed to be that we cannot individuate and identify any particular fact save by using the very same words that we use to individuate and identify its corresponding sentence. There are, however, good reasons for resisting this

line of thought. First, it should be no surprise that we cannot specify a given fact save by means of the sentence to which the fact corresponds, because it could not possibly be otherwise. Suppose our language contained a series of nouns (‘Fact1’, ‘Fact2’ and so on) each referring uniquely to a different fact. We could then use these nouns to identify particular facts, but we could also use these terms to make statements. Any expression that could be used to identify facts could be used to make statements. Second, facts can enter into causal relations in a way that true sentences cannot: the fact that the war was lost caused the government to fall, but the true sentence ‘the war was lost’ cannot cause the government to fall. Third, one of the constituents of the fact that the war was lost is a certain war, but no war (distinct from the word ‘war’) can be a constituent of the true sentence ‘the war was lost’.

Some who would accept the existence of atomic facts would still object to the correspondence theory on the grounds that there are no disjunctive, conditional or negative facts; hence, there are no facts to be the correspondents of true disjunctions, conditionals, or negations. In response to this, a correspondence theorist would rightly note that, on the ordinary sense of fact, it is perfectly correct to say ‘It is a fact that either she gets here on time or I spend the night under a bridge’ or ‘It is a fact that if the donated liver is late, then the patient will die’ or ‘It is a fact that I am not going to make it’. Moreover, a correspondence theory could avoid commitment to conditional, negative or disjunctive facts by giving a recursive analysis of the truth of non-atomic truth bearers.

Truth, deflationary theories of

So-called deflationary theories of truth, of which the best known are the redundancy, performative and prosentential theories, are really theories of truth ascriptions. *This is because they are not theories of what truth* is*; rather, they are theories of what we are saying when we make utterances like '"Routledge editors are fine folks" is true'. The surface grammar of such utterances suggests that we use them to predicate a property, truth, of sentences or propositions; but the several deflationary theories all deny this. Indeed, they all endorse the Deflationary Thesis that there is no such property as truth and thus there is no need for, or sense to, a theory of truth distinct from a theory of truth ascriptions. Thus, for deflationists, the classical theories of truth, such as correspondence, coherence and pragmatic, are not wrong. They are something worse: they are wrong-headed from the start, for they are attempting to analyse something which simply* is not there.

1 Problems with the Deflationary Thesis

What *are* we saying when we make utterances that *appear* to be ascribing truth to some truth bearer? According to the redundancy theory, whose invention is usually credited to F.P. Ramsey, we are saying nothing more or less than what is said in the statement to which we appear to be ascribing truth: '"Routledge editors are fine folks" is true' is synonymous with 'Routledge editors are fine folks' (see Ramsey, F.P. §3). The redundancy theory, then, endorses the view that anything we can say or do with the predicate 'is true' can be said or done perfectly well without that predicate. The latter contention, which I shall call the Gratuity Thesis, is shared by the performative and prosentential theories of truth ascriptions discussed below, although these offer different accounts of what we are saying or doing when we ascribe truth. By itself, the Gratuity Thesis would be of importance only to linguists. Philosophical interest arises because redundancy theorists, and their performative and prosentential counterparts, make a breathtaking and rather cloudy inferential leap from the Gratuity Thesis to the Deflationary Thesis.

The description of the Deflationary Thesis given above seems to presuppose Platonism: that there are universal properties, and most predicates name properties. We can make it neutral with regard to Platonist-Nominalist debates by rewriting it thus: '"is true" is not a genuine predicate'.

It would be absurd to suppose that most predicates are not genuine predicates, so it would be equally absurd to take as a methodological principle that we should assume a predicate is not genuine until it is proven to be. Strangely, however, deflationists have adopted that principle, and anti-deflationists have let them get away with it. Indeed, it was not until the late 1970s and 1980s that the slow decline of ordinary language philosophy brought either contender to an awareness that linguistic analysis alone cannot settle the question (see Ordinary language philosophy §1). If indeed we do not need to postulate a property of truth (whether Platonically or Nominalistically construed) to explain what we are doing with our truth-ascribing utterances, then that is a point in favour of the Deflationary Thesis. But it is not decisive, for there may well be non-linguistic programmes which cannot be carried out without supposing that truth is some kind of property. Anti-deflationists have suggested, for example, that without such a postulation, we cannot explain why our scientific theories are so successful. To this, deflationists have responded that there is really nothing here that needs explanation: we have the theories we do just *because* they are successful. But this will not do. The fact that we would not have automobiles if they did not succeed in getting us from place to place does not preclude the need for an explanation of why they work, which would presumably be given in terms of the properties of automobiles and the forces at work in them.

Explaining the success of science is just a special case of the traditional epistemological programme of discovering the correct theory of justification. The task of the latter project is to refute scepticism by finding some property, called a 'mark' of truth, which correlates, perhaps imperfectly, with truth, and whose possession or non-possession by a given proposition is reasonably easy to detect. Coherence theories of justification (not truth) propose 'coherence with other propositions' as the mark. Foundationalists propose that it is 'self-evident (perhaps defeasibly), or inferred from self-evident premises'. One cannot judge whether a proposed mark does indeed correlate with truth unless one has some notion of what truth *is,* so this programme must postulate that truth is some kind of property. Those few deflationists who have considered this proposal respond by insisting, in effect, that we are entitled just to beg the question against scepticism, and hence there is no need for traditional epistemology in the first place. Begging the question against scepticism has been popular in contemporary

philosophy, but anyone tempted to think that this is philosophically respectable should consider the following analogy: to prove the soundness and completeness theorems for classical logic is, in effect, to prove that the results of the logic's rules of inference correlate (perfectly) with truth (as defined in the logic's model theory). How seriously would we take one who claimed that such proofs (and hence the model theory itself) are unneeded because we are entitled to assume that the inference rules of classical logic are correct? (And how would 'correct' as used here be defined without postulating a property of truth?) Even mathematical intuitionism does not want to say that there is no such thing as truth. It simply defines truth in terms of justification, that is, proof.

2 Problems with the Gratuity Thesis

The intense interest in the Deflationary Thesis in the later decades of the twentieth century should not give the impression that the Gratuity Thesis is itself beyond doubt. All existing theories of truth ascriptions face problems. In particular, at least two of the difficulties confronting the redundancy theory are worth mentioning. First, what are we to make of blind truth ascriptions such as 'What the editor says is true', which do not explicitly identify the proposition to which truth is being ascribed? Given that the speaker (and for that matter the audience) might not even know what proposition the editor has asserted, the idea that this truth ascription is just an alternative way of asserting that same proposition loses some plausibility. The two best redundancy theories, those of C.J.F. Williams (1976) and Paul Horwich (1990), handle this problem quite cleverly. But neither of them deals adequately with the fact that, as Horwich concedes, the redundancy theory cannot actually be stated. It can be *described* as the conjunction of all clauses of the form: '"*p* is true" is synonymous with "*p*"'. Obviously, one cannot state an infinitely long conjunction. Nor can one simply append the quantifier 'For all *p*' to the front of this schema. Such a quantifier cannot be objectual, on the one hand, because the first appearance of the '*p*' in the schema stands in for a noun, while the second appearance stands in for a grammatically complete clause. On the other hand, such a quantifier cannot be substitutional, for then the redundancy theory would be saying 'all substitution instances of the schema are true' and thus the theory would be parasitic on some other antecedent notion of truth.

P. F. Strawson's (1950) performative theory of truth (ascriptions) denies that apparent truth ascriptions say *anything* in any familiar sense of 'say' (see Strawson, P. §4). Such utterances are more *doings* than *sayings*. They are gestures of agreement, much like nodding one's head. Hence, to utter '"Routledge editors are fine folks" is true' is to signal agreement with the notion that Routledge editors are fine folks. Utterances which do something rather than say something are called illocutionary or performative utterances (see Performatives).

Strawson concedes that certain conditions in the non-linguistic world must obtain before one may properly signal one's agreement, where the force of 'properly' is not 'appropriate from the standpoint of honesty or accuracy' but 'appropriate from the standpoint of correct usage'. For example, one ought not utter the words '"The dam has collapsed" is true' unless one believes it is a fact that the dam has collapsed. But if uttering an apparent truth ascription is just to signal agreement, why would the facts of the matter have any relevance? If 'is true' in no way asserts that these conditions are fulfilled, then how and why would these conditions be conditions for uttering 'is true'? One can after all *signal* agreement, dishonestly, even when one does not in fact agree. A second reason for doubting that the performative theory can establish the Gratuity Thesis is that, as H. Price (1988) has pointed out, the theory makes it a mystery why 'is true' is only applicable to indicative sentences. Why can we not use it to endorse the appropriateness of some question (for example, '"Is snow white?" is true') just as we can use it to endorse someone's assertion? And why can we not say '"Shut the door!" is true' to express our endorsement of the importance of obeying this command? It seems that any answer to these questions would have to concede that 'is true', 'is a good question', and 'ought to be obeyed' *mean* different things and this would imply that each of them *says* something.

Besides pronouns, English also contains pro-verbs, such as the 'did' in 'Mary ran quickly, so Bill did too', and pro-adjectives such as 'such' in 'The happy man was no longer such'; and pro-adverbs such as the 'so' in 'She twitched violently and, while so twitching, expired'. D. Grover, J. Camp and N. Belnap (1975), inventors of the prosentential theory of truth (ascriptions), suggest that there are also prosentences. 'So' is used this way in 'I do not believe Rachel is sick, but if so, she should stay home'. More to the immediate point, they contend that the phrases 'it is true' and 'that is true', despite their subject-predicate structure, are really one-word prosentences. And they claim that every locution in which 'is true' appears can be replaced by a locution that uses one of these prosentences. Thus, they endorse a modified version of the Gratuity Thesis: 'is true', as a separable predicate, is a

gratuitous feature of the language. For example, ‘Everything John says is true’ is ‘For every proposition, if John says that *it is true*, then *it is true*’, where neither the ‘it’ nor the ‘is true’ have any separate meaning whatsoever.

The most serious objection to the prosentential theory concerns modified uses of ‘is true’ such as ‘is not true’ or ‘will be true’. The prosentential theory postulates that the deep structure of English contains a number of sentential operators including ‘It-will-be-true-that’ and ‘It-is-not-true-that’, and that all modified uses of ‘is true’ involve one or the other of the two prosentences within the scope of one of these operators. Thus, the deep structure of ‘Everything John says will be true’ is ‘For all propositions, if John says that it is true, then it-will-be-true-that it is true’, where, again, the ‘it is true’ is a prosentence. To analyse apparent predications of falsehood, they postulate the operator ‘It-is-false-that’. Thus, the deep structure of ‘That is false’ is ‘It-is-false-that that is true’. But, then, how do we account for the ‘true’ that appears in the sentential operators? The operators cannot themselves be given a prosentential analysis: if they could, there would have been no need to postulate them in the first place. The use of hyphens to connect the words of the operators tempts us to think of them each as a single word, in which case the ‘true’ in them has no independent meaning. But it is not easy to see how we could explain the meanings of these one-word operators without using a substantive notion of truth, and even if we could, our explanations of such one-word operators would miss out entirely on the common element in the meanings of, say, ‘it-will-be-true-that’ and ‘it-was-true-that’.

Truth, pragmatic theory of

Two distinctly different kinds of theories parade under the banner of the 'pragmatic theory of truth'. First, there is the consensus theory of C.S. Peirce, according to which a true proposition is one which would be endorsed unanimously by all persons who had had sufficient relevant experiences to judge it. Second, there is the instrumentalist theory associated with William James, John Dewey, and F.C.S. Schiller, according to which a proposition counts as true if and only if behaviour based on a belief in the proposition leads, in the long run and all things considered, to beneficial results for the believers. (Peirce renamed his theory 'pragmaticism' when his original term 'pragmatism' was appropriated by the instrumentalists.) Unless they are married to some form of ontological anti-realism, which they usually are, both theories imply that the facts of the matter are not relevant to the truth-value of the proposition.

1 Pragmaticism

C.S. Peirce believed that any two minds investigating a given question would tend eventually to arrive at the same answer, even if they used different methods and different pools of evidence: ' Let any human being have enough information and exert enough thought upon any question, and the result will be that he will arrive at a certain definite conclusion, which is the same that any other mind will reach' (Peirce 1931-58 (7): 319). Moreover, this one answer that all would reach is, by definition, the true answer: ' The opinion which is fated to be ultimately agreed to by all who investigate is what we mean by truth' (Peirce 1931-58 (5): 407). Indeed, in principle, consensus embodies the truth *no matter what method was used to bring about the consensus*. ' If a general belief…can in any way be produced, though it be by the faggot and the rack, to talk of error in such belief is utterly absurd' (Peirce 1931-58 (8): 16). Although Peirce thought that in the long run the only method which could produce and sustain a consensus agreement is what he called 'abduction' (what is now called 'inference to the best explanation'), it is important to remember that he did not think propositions which would be universally accepted are true because they were arrived at by abduction; rather, he thought they are true just because they would be universally accepted (see Peirce, C.S. §3).

Whence Peirce's confidence that investigators would move towards a common conclusion? Ultimately, our evidence takes the form of perceptions, and these perceptions are controlled by a single fixed reality which is public to all. Since there is just one objective reality and it is driving all of us to beliefs that accurately reflect it, we are driven to agree with one another. So, in the long run, the only propositions with which everyone would agree are those that accurately reflect reality. Hence, 'is true' is equivalent to 'accurately reflects reality'. It might seem odd, then, that Peirce turns his attention away from this equivalence and focuses instead on what would otherwise seem to be an incidental equivalence between 'is true' and 'would eventually be agreed to by everyone with sufficient relevant experiences'. But for Peirce it is the former relation which is the trivial one because reality, he thought, is just a construct of the community of human minds. Specifically, what is real is just whatever we would come to agree is real: ' the real is the idea in which the community ultimately settles down' (Peirce 1931-58 (6): 610) and ' everything, therefore which will be thought to exist in the final opinion is real, and nothing else' (Peirce 1931-58 (8): 12). Peirce called this his 'social theory of reality'.

But notice now how this ontological doctrine undermines Peirce's own explanation for why all who investigate a given question would ultimately come to agreement: on a realist ontology, the notion of reality controlling our perceptions is based on common sense; but on the social theory of reality, it is an idea in the minds of those who have already reached the final opinion which is causing those who have not reached it to have certain perceptions. Indeed, matters are even stranger than this; for the very perceptions that caused those who have reached the final conclusion to reach it were forced on them, *in a reverse-chronological direction*, by the final conclusion which, at the time they had the perceptions, they had not reached. Therefore, some of the perceptions you and I are having right now are forced on us by an idea which, if we have it at all, we will only have at some future time. Peirce himself was aware of this rather fantastic implication of his views and attempted to defend it:

At first sight it seems no doubt a paradoxical statement that, ' The object of final belief which exists only in consequence of the belief, should itself produce the belief';…there is:

> nothing extraordinary…in saying that the existence of external realities depends upon the fact, that opinion will

> finally settle in the belief in them. And yet that these realities existed before the belief took rise, and were even the cause of that belief, just as the force of gravity is the cause of the falling of the inkstand - although the force of gravity consists merely in the fact that the inkstand and other objects will fall.
>
> (Peirce 1931-58 (7): 340-4)

But this will not do. On the analysis of causation which Peirce is assuming, the relation between gravity and the tendency of things to fall is one of identity, not of mutual causation. Moreover, even if we allow that gravity is in some sense a consequence of the fact that things tend to fall, neither gravity nor the tendency are events in time. Hence, to assert that the former is both a cause and a consequence of the latter is not to assert the possibility of reverse-chronological causation. But coming to believe the final conclusion, and the occurrence of the perceptions that bring about that belief, are both events in time, and they come at different times. Hence, to assert that the chronologically earlier of these is caused by the chronologically later is to assert something not at all analogous to any causal relations involving the inkstand.

The problems in Peirce’s account go even deeper. Although Peirce sometimes speaks as if the final conclusion is fated or destined, on those occasions on which he self-consciously considers whether this conclusion will ever actually be reached, he is much more cautious: ‘ We cannot be quite sure the community will ever settle down to an unalterable conclusion upon any given question…nor can we rationally presume any overwhelming *consensus* of opinion will be reached upon every question’ (Peirce 1931-58 (6): 610).

> I do not say that it is infallibly true that there is any belief to which a person would come if he were to carry his inquiries far enough. I only say that that alone is what I call Truth. I cannot infallibly know that there *is* any truth.
>
> (Peirce 1966: 398)

So the causal action of the final conclusion on our present actual perceptions is not only reverse-chronological, it is also action from within a hypothetical domain to the actual domain.

2 Instrumentalism

William James always claimed to accept the definition of truth embodied in correspondence theories of truth, namely that a true belief or statement is one that ‘agrees with reality’ (see James, W. §5). But, for James, the reality to which true ideas must agree is mind-dependent: ‘ By "reality" humanism [one of James’s names for his philosophy] means nothing more than the other conceptual or perceptual experiences with which a given present experience may find itself in point of fact mixed up’. And, ‘ we are not required to seek [truth] in a relation of experience as such to anything beyond itself’. And, ‘ reality is an accumulation of our own intellectual inventions’. These inventions include ‘ the notions of one Time and of one Space as single continuous receptacles; the distinction between thoughts and things, matter and mind; between permanent subjects and changing attributes; the conception of classes with sub-classes within them; the separation of fortuitous from regularly caused connexions’. Unlike Kant, however, James does not think that these constructs are built into our minds. Rather, these constructs are inventions of our ancestors. They *made* the world this way, by so conceiving of it. Why did they choose to structure the world with these features and not some other features? James’s answer is that they found it more *useful* to organize the world in this manner. The last quotation continues:

> surely all these were once definite conquests made… by our ancestors in their attempts to get the chaos of their crude individual experiences into a more shareable and manageable shape. They proved of such sovereign use as *denkmittel* [instruments of thought] that they are now a part of the very structure of our mind.
>
> (James 1909: 42)

James also wants to give the word ‘agree’, in the phrase ‘agrees with reality’, a different sense from the typical correspondence theorist. Given that reality is just useful mental constructs of the collection of past and present minds, a belief agrees with reality by proving useful to those who believe it. The examples James offers suggest that useful beliefs are those which: (1) enable us to manipulate the objects of the world; (2) allow us to communicate successfully with our fellows; (3) provide good explanations for other occurrences; and (4) lead to accurate predictions.

It should be kept in mind, if for no other reason than to forestall overly facile counterexamples, that James identifies truth with beliefs that are useful over the long run and all things considered:

> ‘"*The true*",*to put it very briefly, is only the expedient in the way of our thinking, just as "the right" is only the expedient in the way of our behaving.* Expedient in almost any fashion; and expedient in the long run and on the whole of course; for what meets expediently all the experience in sight will not necessarily meet all farther experiences equally satisfactorily’
>
> (James 1907: 106)

Still, opponents of instrumentalism would insist, it might be useful throughout a person’s life for them to believe that they are better at their job than anyone else (because, for example, the increased confidence it gives them pays huge dividends.) And this can be the case even if they are not in fact better at their job than anyone else. James, however, denied that there can be any cases in which the truth and the facts are disjoint, and the reason for his denial lies in his ontology: if the facts are themselves just mental constructs which have proved useful, then there cannot be a case of a useful belief that does not agree with the facts.

So, both Peirce and James can happily accept what have been called ‘T-sentences’ - sentences of the form ‘"p is true" if and only if p’. But for both of them, this coordination of truth and reality is itself an incidental side effect which distracts from, rather than reveals, the essential nature of truth.

Truthfulness

Humans are the only species capable of speech and thus of lies. Choices regarding truthfulness and deceit are woven into all that they say and do. From childhood on, everyone knows the experience of being deceived and of deceiving others, of doubting someone's word and of being thought a liar. Throughout life, no moral choice is more common than that of whether to speak truthfully, equivocate, or lie - whether to flatter, get out of trouble, retaliate, or gain some advantage.

All societies, as well as all major moral, religious and legal traditions have condemned forms of deceit such as bearing false witness; but many have also held that deceit can be excusable or even mandated under certain circumstances, as, for instance, to deflect enemies in war or criminals bent on doing violence to innocent victims. Opinions diverge about such cases, however, as well as about many common choices about truthfulness and deceit. How open should spouses be to one another about adultery, for example, or physicians to dying patients? These are quandaries familiar since antiquity. Others, such as those involving the backdating of computerized documents, false claims on résumés in applying for work, or misrepresenting one's HIV-positive status to sexual partners, present themselves in new garb.

Hard choices involving truthfulness and lying inevitably raise certain underlying questions. How should truthfulness be defined? Is lying ever morally justified, and if so under what conditions? How should one deal with borderline cases between truthfulness and clear-cut falsehood, and between more and less egregious forms of deceit? And how do attitudes towards truthfulness relate to personal integrity and character? The rich philosophical debate of these issues has focused on issues of definition, justification, and line-drawing, and on their relevance to practical moral choice.

1 Truth, truthfulness, falsity and deceit

By what criteria can we distinguish between truthfulness and deceit? Should all deceptive messages, whether intended to deceive or not, whether verbal or nonverbal, count as lies so long as they end up misleading recipients? Such an all-encompassing view is unpersuasive: it is hard to claim that erroneous weather forecasts, for example, or promises people make in good faith but are later unable to honour, constitute lies.

If one limits the category of lies to intentionally false speech, however, problems arise about how to characterize the use of metaphor and other figurative speech, rhetorical flourishes, and works of fiction (see Metaphor; Fictional entities; Art and truth §2). Some thinkers have been known to hold that the very purpose of all art, including fiction, is to deceive: they may defend the practice, as Oscar Wilde does in 'The Decay of Lying' (1892), suggesting that, 'the final revelation is that Lying, the telling of beautiful untrue things, is the proper aim of Art'; or deplore it, as does Socrates in Plato's *Republic*, when he argues that poets mislead their audiences in speaking, for instance, of the gods as undignified or immoral. Many people, rejecting the view that fiction must involve lying, prefer to limit the category of lies to spoken communication intended to mislead. They take what Samuel Coleridge called 'the willing suspension of disbelief' (1817: 6) to operate in such a way that fiction does not count as deceitful, and may regard persons who cannot distinguish between lies and fiction as obtuse. Thus John Stuart Mill pointed to Jeremy Bentham's aphorism 'All poetry is misrepresentation' as revealing his literalness and his impoverished understanding of human nature (1838: 50-1).

The failure to sort out such disagreements about the scope of definitions generates needless confusion in debates about truthfulness and deceit. In turn, this failure risks perpetuating a conceptual muddle with regard to the crucial differences between the *moral* domain of intended truthfulness and deception and the *epistemological* domain of truth and falsity. The moral question of whether you are lying or not is not *settled* by establishing the truth or falsity of what you say. In order to settle this question, we must know whether you intend your statement to mislead those to whom you address yourself. The two domains often overlap; but truth and truthfulness are not identical, any more than falsehood and falsity (see Aquinas, *Summa theologiae*). Confusing the domains of 'truth' and 'truthfulness' has especially problematic consequences for persons whose scepticism about all epistemological claims concerning truth bleeds into their attitudes with respect to the moral questions about deceit and truthfulness. They may leap from doubting that we can ever know the full truth about anything to doubting that there are differences between aiming to lie or to speak truthfully, and in turn to regarding all communication

as equally unreliable. Iris Murdoch, in *Metaphysics as a Guide to Morals* (1992: 198), discusses how structuralists make this leap with regard to history, thus blotting out 'the conception of seeking carefully for some truthful conception of the past'. 'Fabulation' means providing accounts in the form of fables, as did Ovid, or, more generally, to concoct and fabricate. 'Confabulation' has come into common parlance as a psychiatric term so recently that it has yet to be recorded in a major dictionary. The term, which used to carry the meaning of persons simply coming together to talk or chat, is now used to refer to the stories told by brain-damaged persons suffering from Alzheimer's disease and a variety of other psychiatric and neurological conditions. They may spin false tales about their lives with great aplomb and in utter confidence that they are correct. They cannot, therefore, be thought of as engaging in lying or any form of deceit; at the same time, because their statements depart so clearly from the truth, it is difficult to speak of truthfulness in characterizing their stories.

Such cases show that the moral dimensions of choices concerning truthfulness and deceit are not exhausted by referring to the intentions of those who make statements. There is a large category of statements where deceit is not intended but where truthful communication is far from being achieved. In exploring this category, it is important to take into account all that can help to distort communication quite apart from an intention to deceive. When people convey false information in the belief that it is true, they may be tired, mistaken, uninformed, inarticulate, intoxicated, or duped by others; but so long as they do not intend to mislead anyone, they are not acting in a manner that is in any way deceitful. Their statements may be false, but they have not knowingly uttered falsehoods. If the information is conveyed through intermediaries, as through gossip or via the media, further distortion from such causes is likely to ensue. At the receiving end of such information, likewise, similar factors and others such as deafness may operate so that people end up deceived through no fault of the person who originated the message or those who passed it along.

Allowing for these qualifications, a truthful person is someone who aims consistently to speak so as not to mislead others. A scrupulously truthful person is one who takes special care to try to counteract factors known to skew or distort communication. The trait of 'truthfulness', defined as the disposition to tell the truth, is widely regarded as a virtue. Truthfulness can take either the baseline form of avoiding all lies or the wider form of being as forthcoming and sincere as possible at all times. The fourth Buddhist Precept of Right Action spans this spectrum, in enjoining followers of Buddha 'not to lie but to practice sincerity and honesty'. And Michel de Montaigne, who took a firm stance against lying and all forms of deceit, put the difference as follows: 'We must not always say everything, for that would be folly; but what we say must be what we think; otherwise it is wickedness' (1533-92: 401).

The disposition to be truthful is generally held to be both admirable in its own right and central to the larger cluster of traits called honesty. 'Honesty' characterizes a person of integrity and trustworthiness who avoids not only lies and intentional deception, but also theft, cheating, plagiarism and other forms of duplicity and betrayal. Conversely, 'dishonesty' refers to the disposition to lie, deceive, steal, cheat and defraud more generally. 'Veracity' is often used synonymously with 'truthfulness', in the above sense, but carries an additional stress on the accuracy of what is stated.

Just as false statements need not be deceitful, moreover, so true statements can sometimes be meant to deceive. An isolated true statement told by someone known to be a habitual liar can be intended to mislead listeners, and succeed in doing so, as much as lies by persons thought honest. Persons adept at producing 'information overload', moreover, as in lengthy, confusing sales agreements or insurance documents, can aim to deceive others without actual lies.

Withholding part of the information needed by interlocutors, finally, can be as deceptive as any lie. Sellers of medications, toys or automobiles who purposely omit information regarding dangerous defects or other risks attendant on using their products, engage in such deceit. So do investigators who enrol patients in studies of experimental drugs without asking for their fully informed consent. Persons wishing to engage in such communications while at the same time maintaining that they adhere strictly to the truth have often had recourse to the concept of a 'mental reservation'. It involves speaking only a partial but highly misleading truth with the intent to deceive, while adding in one's mind the missing words that would render the statement non-deceptive: as, for instance, when a thief responds to an inquiry about a theft the previous week by claiming that he had not stolen anything, adding silently 'today'.

2 Justification

From the Bible's Ten Commandments to the Buddhist Five Precepts for Right Action, from the Five Jaina Great Vows to the Hindu prescriptions in the *Bhagavadgītā* (see Bok 1996), from the maxims of Confucius to the dictates of the Roman Stoics, false speech, along with the resort to violence, has been rejected consistently. However much these traditions differ over questions of religious belief, asceticism or sexual conduct, they speak in unison in condemning violence and lies, the two ways by which human beings deliberately bring about injury to one another. Because no society or human relationship could survive without at least a degree of truthfulness in communication, all communities have stressed truthfulness as a trait to be fostered, at least with respect to intimates, friends and colleagues. Even the devils themselves, as Samuel Johnson said, quoting Sir Thomas Brown, do not lie to one another: truth is as necessary to their society as to all others (see Hindu philosophy; Jaina philosophy; Confucian philosophy, Chinese; Stoicism).

Even so, the world's traditions rest their preference for truthfulness and their condemnations of deceit on widely differing forms of justification. They may claim a variety of religious reasons for condemning lying, argue that it goes against the natural order, hold that it jars with our 'moral sense', or invoke other reasons. Further differences arise within each tradition with respect to whether or not exceptions are permitted under certain circumstances, and, if so, which ones and on what grounds. Is it excusable to lie, for example, where truthfulness might endanger innocent persons, precipitate violence, or cause despair? Or possibly even justifiable?

While a degree of truthfulness has been recognized as necessary everywhere, the pull of lying has been ever-present. It offers the simplest and most tempting way of trying to generate false beliefs among listeners and thus of achieving power over them or eluding their power over oneself. But because truthfulness is uniformly seen as the norm and lies as morally problematic, the burden of proof falls on those who would defend particular categories of departures from truthfulness.

Two positions have been taken within most traditions on this score. The first, absolutist, position was held by, among others, Augustine and Immanuel Kant, who took there to be no sufficient justification for lying. According to Augustine, lies can be ranked according to their severity, with lies about God the most severe and lies by a virgin to guard against violation the most excusable. Such excusable lies, while not mortal sins unlike the former, are nevertheless forbidden by God and should be avoided. Kant (1788) also rejected all lies as unjustifiable and recognized, under the heading of 'casuistical questions', cases of seemingly more excusable lies; but he refused to rank them as Augustine had done. He insisted, instead, that truthfulness is an unconditional duty which holds in all circumstances. All persons who lie, he claimed, thereby repudiate their own human dignity and contribute to undermining the precarious trust on which human society is based.

The second position is shared by many thinkers who set forth certain types of lies as excusable or even justifiable. Some of them argue that lies to certain kinds of people - children, the dying, the mentally ill, or enemies in war - should not count as lies properly speaking, and are justifiable whenever told to deceive these persons for their own good or in self-defence. There is no need for complex moral reasoning in such cases, these writers claim. Thus Hugo Grotius (1625) held that falsehoods told to children or to the insane show no disrespect for their liberty of judgment, since they have no such liberty in the first place. Others argue that lies *by* certain persons are justified in the exercise of their professions, as in the law or policing or medicine or, as urged by Machiavelli in *Il principe (The Prince)* (1532), governing (see Machiavelli, N. §2). While they agree that high standards of honesty should be encouraged in most walks of life, these advocates maintain that there are special circumstances and pressures within their own profession that necessitate forgoing candour at times. Important goals such as the interests of one's nation or one's clients, the public welfare, the advancement of knowledge, or the uncovering of corruption, may be at stake, and may outweigh a strict commitment to veracity.

John Stuart Mill argued, on utilitarian grounds, that it is possible so to estimate the consequences of particular lies as to sort out those few lies that would be justifiable (see Utilitarianism; Consequentialism). Henry Sidgwick (1874) likewise concluded on such grounds that certain lies are justifiable - among them those told to invalids where the truth might prove too great a shock to them. W.D. Ross (1930) held that, while there is a *prima facie* duty of fidelity, which includes that of veracity, it can conflict with other *prima facie* duties such as that of 'not injuring others'. It is worth noting, however, that Mill and Sidgwick both took seriously what Kant also emphasized but Machiavelli did not: the central importance of the virtue of veracity for purposes of societal trust.

3 Line-drawing

Problems of line-drawing will always arise with respect to the interlocking distinctions having to do with truth, truthfulness, falsity, and deceit, both when it comes to definitions and forms of justification or excuse. In considering definitions, first of all, just where should the boundaries be between intentional and unintentional deception? Or between jokes understood as such by all listeners and tricks meant to mislead them? Or between mild exaggeration and outright lies? Are so-called white lies even lies in the first place? When do errors due to poor memory shade into confabulation? When does the transmission of false information - say by reporters covering public officials - shade into complicity in deceit? How easy is it even for historians to tell when they are engaged in conscious rewriting of history, let alone their readers? And in evaluating possible justifications for accepting or ruling out lying, by what means might a Kantian best distinguish intentionally and unintentionally deceptive statements? How might Grotius compare what degree of truth is owed to preadolescents? How do Ross and others weigh conflicting *prima facie* duties in marginal cases? And how should utilitarians weigh the gains or losses that will flow from comparatively similar forms of deceit?

From the earliest texts onward, the moral perplexities in trying to sort out and compare forms of deceit have been set forth: as in the account of Adam and Eve and the serpent in Genesis, the kiss of Judas in the New Testament, the false protestations of lifelong truthfulness in the Egyptian *Book of the Dead*, or the trickery of Ulysses in Homer's *Odyssey* and *Iliad*. And thinkers in the great traditions of casuistry and practical moral inquiry - among them Confucians, Stoics and commentators on Christian, Jewish, Buddhist, Hindu and Islamic ethics - have worked to weigh the difficult 'cases of conscience' in which the duty not to lie appears to conflict with such duties as that of keeping promises of secrecy or saving intended victims from murderers.

Drawing lines with respect to truthfulness and deceit often turns out differently, however, depending on whose choices are being considered. Truthfulness is a trait that people tend to prize more in others than regard as fully called for when it comes to their own choices. When they consider themselves as being on the receiving end of other people's lies, they are more suspicious of the underlying motives than when they weigh possible lies of their own. Each of these perspectives on truthfulness and deceit - that of the deceived and that of those considering engaging in deception - is incomplete, biased, and undiscriminating by itself. The perspective of those who see themselves as at the receiving end of lies is, understandably, suspicious in the extreme. As a result, they are more likely to blur the distinction between errors and lies, between the honest and the dishonest, between intended and unintended injuries. By contrast, the perspective of those who wonder whether or not to lie blurs and confuses the harm that lying does not only to those lied to but also to those who do the lying, and, most insidiously and indelibly, to trust. To persons adopting this latter perspective, lies may seem far more excusable or innocuous and the risks of discovery or of slipping into broader practices of deceit less worrisome.

It is only by examining one's choices not only as subject and agent but as recipient, sometimes victim, that a fuller perception of truthfulness and lying becomes possible, and of ways to counteract the biases present in each of the perspectives. These biases operate not only to skew line-drawing when it comes to defining truthfulness and lying, but also with respect to justifying or excusing particular choices. In this way, those considering lies of their own may give themselves far more latitude than they grant to others in declaring certain forms of duplicity such as white lies nondeceptive; and greater latitude, too, when it comes to excusing or justifying what they acknowledge as lies.

Both Kant, who characterized lying as a repudiation of one's own human dignity, and Mill, who wrote in *Utilitarianism* (1861) of the need to cultivate in oneself a 'sensitive feeling on the subject of veracity', addressed, albeit from different points of view, the importance of taking truthfulness seriously in one's own life. The role that one assigns to truthfulness, they both thought, should be central in considering what kind of person one wants to be - how one wishes to treat not only other people, but oneself. Everyone can make mistakes when it comes to truthfulness and deception and be swayed by poorly understood forces and temptations; it is another matter altogether to choose to be someone who deals with others through deceit. Such a choice is made easier by neglecting to take these forces and temptations into adequate account. Though Mill would have insisted on certain rare exceptions to what he characterized as the 'sacred rule' of veracity, he might otherwise have concurred in Kant's linking internal and external truthfulness, in the last of his books published in his lifetime, *Anthropology from a Pragmatic Point of View* (1798: 207): 'Briefly, as the highest maxim, uninhibited internal truthfulness

toward oneself, as well as in the behavior toward everyone else, is the only proof of a person's having character.'

Tschirnhaus, Ehrenfried Walther von (1651-1708)

The natural philosopher E.W. von Tschirnhaus emphasized bodily and mental health, was a friend of Spinoza and correspondent of Leibniz. He perfected the construction of concave mirrors (used to generate extremely high temperatures) and was probably the first European to produce porcelain. Hoping to make scientific progress more predictable, Tschirnhaus devised a method of inquiry orientated to mathematics and experimentation.

Ehrenfried Walther (Walter) von Tschirnhaus was born in Kieslingswalde, east of Dresden, on the family's estate. After studying medicine and science at the University of Leiden, he went on extended educational travels. In 1682, he was elected the first German member of the Académie Royale des Sciences in Paris for his chemical experiments and innovations in making burning mirrors. Upon returning to Kieslingswalde, Tschirnhaus built a laboratory and tried to unlock the secrets of porcelain production. He died shortly after the decisive experimental breakthrough. Ludwig Böttger, his assistant and co-worker, passed himself off successfully as the sole inventor of European porcelain after Tschirnhaus' death.

The general theme of Tschirnhaus' writings is the achievement of bodily and mental health. Mental health consists in a state of wisdom, tranquillity and happiness. This state results from the striving for self-perfection through scholarly study, intellectual creativity and scientific discovery.

The *Medicina Corporis (Medicine for the body)* (1686) was Tschirnhaus' first book, comprising twelve rules for a physically healthy life. His second and main work was the *Medicina Mentis (Medicine for the mind)* (1687). It contains a methodology for a philosophy of nature based on experimentation and deduction. The oblique but nonetheless obvious references to Spinoza in the *Medicina Mentis* prompted Christian Thomasius to charge Tschirnhaus with heresy and Spinozism, to which the accused replied with *Eilfertiges Bedencken* (1688). Tschirnhaus' later treatises are devoted to pedagogy: the *Gründliche Anleitung zu nützlichen Wissenschafften (The select primer of useful sciences)* (1700), on the scientific education of young people, and *Dreissig Hinweise für einen guten Hofmeister (Thirty suggestions for a good steward)* (1704, published posthumously 1727), on the general education of gentlemen and court officials. He also published a variety of mathematical papers in the *Acta Eruditorum*, founded in Leipzig in 1686. However, the errors these contained did more harm than good to Tschirnhaus' reputation.

Since mathematics is the most successful of all sciences, Tschirnhaus argued, like Descartes, that the scientific investigation of nature ought to follow the example of mathematics and adopt its deductive methods. Although mathematics is abstract, dealing solely with notional entities, it can and should be applied to the study of material entities occurring in nature. Physics is most successful when quantitative. The study of nature ought to start with the classification of evident truths about the object under investigation. Empirical features of the object should be identified by experiments that are to be performed systematically, according to rules. Ideally, a complete list of all relevant data will then be generated, containing the basic notions (*primi conceptus* or definitions) of the object under investigation. Individual definitions yield axioms, combined definitions yield theorems, and the statements so deduced constitute the exhaustive knowledge of the object.

Tschirnhaus has often been misunderstood. Christian Wolff, who claimed to have been influenced by him, took this methodology of natural philosophy as an apology for the so-called geometric method of metaphysics. Wolff held that philosophy can imitate mathematics in style without employing it in content, and aprioristic non-quantitative deductions are permissible without experimental confirmation. Twentieth-century Marxists regarded Tschirnhaus as a spiritual forerunner, whose alleged atheism was illustrated by his Spinozist sympathies and whose putative social awareness was indicated by his interest in practical questions of engineering and manufacturing.

Tsong kha pa Blo bzang grags pa (1357-1419)

Tsong kha pa Blo bzang grags pa (Dzongkaba Losang dragba), the founder of the dGa'-ldan-pa (Gandenba) school of Tibetan Buddhism, was born in Tsong-kha, in the extreme northeastern region of Tibet. He is often depicted as a type of reformer, putting great emphasis on moral precepts and interpreting Tantra in a way which would not create any conflict with the traditional Mahāyāna doctrines found in the sūtras *and treatises. He was also an eclectic, drawing upon and synthesizing numerous different currents of Indian Buddhism - for example, he put forth a version of Čast;Prāsaōgika-Mādhyamika which was inextricably bound up with the logical tradition of Dignāga and Dharmakīrti. On the Tibetan side, one of his major philosophical debts was undoubtedly to the gSang-phu (Sangpu) traditions stemming from the highly original thinker Phya pa Chos kyi seng ge (Chaba Chögyi sengge, 1109-69). Finally, his dGa'-ldan-pa school subsequently became the dGe-lugs-pa (Gelukba), a predominantly monastic tradition which in time became the dominant current of Buddhism in Tibet. Tsong kha pa thus had, in addition to his philosophical influence, a long-term impact on the Tibetan political situation, contributing to the transfer of power from the southern provinces to the Lhasa region and laying the groundwork for the peculiarly Tibetan synthesis of religion and political power which was to be embodied in the institution of the Dalai Lamas.*

1 Life and works

The education of Tsong kha pa Blo bzang grags pa (Dzongkaba Losang dragba) was characterized by a series of stays at various monasteries, where he studied the principal philosophical treatises of Indian Buddhism as well as the root texts and commentaries of Tantra. His scholastic knowledge was regularly tested and refined through debate, but equally he engaged in long periods of analytic meditation and in meditative retreats devoted essentially to Tantric practices and rituals. Among the figures who played a role in Tsong kha pa's intellectual development, two are particularly prominent: Red mda' ba gZhon nu blo gros (Rendawa Shönnu lodrö, 1349-1412), who taught him, *inter alia*, Prajñāpāramitāphilosophy, Abhidharma and Mādhyamika; and a certain dBu ma pa (Umaba), who seems to have been, for some time at least, the intermediary for Tsong kha pa to question the bodhisattva Mañjuśrī and thus to come to definite convictions on various matters, including the superiority of Čast;Prāsaōgika-Mādhyamika to all other views. While Red mda' ba is relatively well known to us, and some of his works are still extant, Lama dBu ma pa remains an obscure figure.

Tsong kha pa's *Collected Works* span eighteen Tibetan volumes (from volume *ka* to *tsha*), with about nine volumes (*ga* to *na*) devoted to Tantra, and the other volumes devoted to Mādhyamika, monastic discipline, Prajñāpāramitātopics, rituals, and miscellaneous works and letters. His most famous work is probably the voluminous *Lam rim chen mo (The Great Work on the Stages of the Path*, volume *pa*), a summa of Buddhist thought which was written as an elaborate and loose commentary on Atīśa's *Bodhipathapradīpa (The Lamp for the Path to Enlightenment)*. Equally extremely important is *Drang nges legs bshad snying po (The Essential Correct Explanation of Intentional and Definitive Meaning*, volume *pha*), a later work where we find Tsong kha pa's position on the classification of scriptures as being of definitive (*nītārtha*) or intentional (*neyārtha*) meaning; the work gives his stance on his use of Indian sources and was written largely as a response to Jo-nang-pa (Jonangba) hermeneutics. His major Mādhyamika works are his commentaries on Candrakīrti's *Madhyamakāvatāra (Introduction to the Middle Way*, volume *ma*) and on Nāgārjuna's *Mūlamadhyamakakārikā(The Fundamental Treatise on the Middle Way*, volume *ba*). In Tantric exegesis, besides several commentaries on the *Guhyasamājatantra*, *Cakrasaṃvara*, *Pañcakrama (The Five Steps)*, and so forth, he is well known for his great compendium, the *sNgags rim chen mo (The Great Work on the Stages of Tantra*, volume *ga*). Although Tsong kha pa lectured on logic and epistemology (*tshad ma*), curiously enough he did not write any major works on these subjects; the few texts in his *Collected Works* concerning *tshad ma* are (with perhaps one exception) notes of his teachings taken down by his two closest disciples, rGyal tshab Dar ma rin chen (Gyeltsap Darma rinchen, 1364-1432) and mKhas grub dGe legs dpal bzang po (Kaydrup Gelek belsangbo, 1385-1438). It is, none the less, abundantly clear that his positions on the soteriological import of Dharmakīrti's *Pramāṇavārttika (Commentary on Valid Cognition)*, on the nominalist theory of language and on the importance of Dharmakīrtian logic generally (even for a Mādhyamika), constitute some of the most fundamental elements of his thought (see Dharmakīrti).

2 Elements of Tsong kha pa's Mādhyamika

Tsong kha pa advocated what might be called a ‘minimalist’ Mādhyamika, with no place for the type of Absolute that one finds in the synthesis of Mādhyamika and Buddha-nature doctrines developed by rival Tibetan Mādhyamika schools, notably those of a gZhan-stong-pa (Shendongba) orientation. For him, contrary to gZhan-stong schools, Mādhyamika’s analysis of the inconsistency of phenomena was not designed to prove the existence of an Absolute free of phenomenal qualities, but rather to lead to an understanding of the principle of dependent origination (*pratītyasamutpāda*), the thoroughly relative nature of the phenomena themselves. His *brTen ’grel bstod pa (Praise of Dependent Origination*, volume *kha*), a short text in verse, is often cited as an eloquent statement of this theme.

Undoubtedly, one of the major issues of Mādhyamika philosophy for Tsong kha pa is the question of precisely what and how much Mādhyamikas should deny if they are to avoid reification of entities, yet preserve conventional truth. How one stands on this matter - in particular, how one ‘recognizes the object to be negated’ (*dgag bya ngos ’dzin*) - is argued to have very wide-ranging consequences: it will, *inter alia*, significantly affect the exact formulations of the logical arguments which the Mādhyamika uses, and will even determine the importance that one attaches to analysis and conceptual thought in the quest for spiritual realization. Other important aspects of Tsong kha pa’s Mādhyamika philosophy can be summarized in a series of recurring concepts known as the ‘eight difficult points’. These form the subject matter of a short work, the *dKa’ gnad brgyad kyi zin bris (The Résumé of [Tsong kha pa’s teaching on] the Eight Difficult Points)*. In the opening section he says:

> Concerning the [ontological] bases, there are the following [three points]: (1) the conventional nonacceptance of particulars and of (2) the storehouse consciousness, and (3) the acceptance of external objects. Concerning the path, there are the following [four points]: (4) the nonacceptance of autonomous reasonings as being means for understanding reality and (5) the nonacceptance of self-awareness; (6) the way in which the two obscurations exist; (7) how it is accepted that the Buddha’s disciples and those who become awakened without a Buddha’s help realize that things are without any own-nature. Concerning the result, there is: (8) the way in which the *buddhas* know [conventional] things in their full extent. Thus, there are four accepted theses and four unaccepted theses.
>
> (Volume *ba*-, 1b-2a; translation by T.J.F. Tillemans)

Some of these points are arguably quite faithful to the Indian positions, but others - such as (2), the rejection of the usual Buddhist ideas about latent karmic tendencies being transmitted from life to life via some type of medium like the ‘storehouse consciousness’ in favour of a mere continuum of causally efficient cessations with no medium of transmission whatsoever - are extraordinarily creative developments with fairly little or no grounding in Indian sources (see Buddhism, Yogācāra school of §§5-8). Almost needless to add, they were also very controversial in Tibet. Indeed, Tsong kha pa was savagely mocked by one of his opponents, Go ram pa bSod nams seng ge (Goramba Sönam Sennge, 1429-89), for formulating his Mādhyamika with reliance upon deceptive ‘visions’ of Mañjuśrī, coming to him second-hand via dBu ma pa, rather than upon actual Indian texts.

Although he was a staunch follower of Nāgārjuna and Candrakīrti, Tsong kha pa remained uncompromisingly committed to having philosophical theses and doctrinal positions, and in this respect too he was significantly different from most other Tibetan Mādhyamika philosophers. A singular feature of his approach was that while Čast;Prāsaōgika was the school that he professed, he remained uncomfortable with the usual Indo-Tibetan version of *prasaōga*-method, namely a systematic *reductio ad absurdum* which was required only to refute adversaries by pointing out internal inconsistencies in their views, and did not have to establish true propositions. Repeatedly, Tsong kha pa argued that it was not possible to lead an adversary to a correct view on the basis of arguments which were not supported by some means of valid cognition (*pramāṇa*): as a result, the ‘adversary-established reason’ (*gzhan grags kyi gtan tshig*) could not be established *only* for the adversary; it also had to be, in some way, actually valid and established for the Mādhyamika proponent. Not surprisingly, he was also attacked by critics on this. Go ram pa, in his *lTa ba’i shan ’byed (Differentiation of the Views*, 31b-32a), accused Tsong kha pa of transforming Čast;Prāsaōgika methods into a logic like that of the Čast;Svātantrikas, who maintained that reasoning had to follow the strictures of Dignāga and Dharmakīrti, that is, that the terms had to be established for both parties in the debate.

3 Tsong kha pa on Tantra

Tsong kha pa’s Tantric system was mainly based on the textual cycles of the divinities Guhyasamāja, Saṃvara and Vajrabhairava. Though the majority of his writings were devoted to Guhyasamāja and Saṃvara, Vajrabhairava did have a marked importance for him. Vajrabhairava was Tsong kha pa’s tutelary deity (*yi dam*) from the time of his ordination as a novice monk and represented the fierce aspect of Mañjuśri, who, as we have seen, played such a recurring role in Tsong kha pa’s choices of philosophical orientation. As for the Guhyasamāja cycle, which was without a doubt the main Tantric cycle to which he devoted his attention, Tsong kha pa relied here upon the Indian exegetical system known as the ‘Ārya tradition’, believing (as did most other Tibetan scholars) that the authors of the fundamental treatises of this tradition, namely Nāgārjuna, Āryadeva and Candrakīrti, were identical with the famous Mādhyamika philosophers of the same name. In choosing the Ārya tradition, then, Tsong kha pa seems to have sought to reinforce his basic methodological standpoint that both Tantric and non-Tantric Buddhism had to be understood according to the Čast;Prāsaōgika philosophy of Candrakīrti.

In many respects, however, Tsong kha pa’s Tantric system owes much to syntheses with cycles other than Guhyasamāja. The instructions on the ‘veins’ (*nāḍī*), ‘energy centres’ (*cakra*) and ‘inner heat’ (*caṇḍālī*), all of which play an important role in Tsong kha pa’s views on Tantra, are, notably, virtually absent in the fundamental Indian texts of the Ārya tradition on Guhyasamāja. Rather, we must look to the *Nāro chos drug (Six Teachings of Nāropa)*, a later Indian synthesis of diverse Tantric practices, as having influenced Tsong kha pa in this regard. Indeed, it was the *Pañcakramasaṃgrahaprakāśa (Illumination of the Summary of the Five Steps)*, a short treatise attributed to Nāropa (956-1040) combining the Six Teachings with the ‘Five Steps’ (*pañcakrama*) of the Ārya tradition, which provided Tsong kha pa with the basic ideas of his Tantric system.

Tucker, Abraham (1705-74)

Like many of his eighteenth-century British contemporaries, Abraham Tucker was an empiricist follower of John Locke. Tucker held that the mind begins as a blank slate and remains nothing more than a passive receptacle for 'trains' of ideas with 'a motion of their own'. In his moral philosophy Tucker proposed that the motive of all our actions is the prospect of our own satisfaction, and that the maximization of everyone's satisfaction is the ultimate moral good. (The latter view became a central tenet of the utilitarians who followed him.) According to Tucker, God ensures that our self-interested motivation will be congruent with morality, for God has arranged that we will be rewarded for good and punished for evil - either in this world or in the next. Among those most influenced by his work was the utilitarian and philosophical theologian William Paley.

1 Life

Abraham Tucker was born in London to wealthy parents in 1705. His father died during Abraham's infancy, and an uncle, Isaac Tillard, became his guardian. Tucker studied law at Oxford, but never practised. At 22, he purchased Betchworth Castle; at 31, he married Dorothy Barker, with whom he had two daughters.

Tucker's most significant philosophical work is *The Light of Nature Pursued*, published under the pseudonym Edward Search. A preliminary version of this work appeared in 1763 under the title *Freewill, Foreknowledge, and Fate*, but the full seven volumes of *The Light of Nature Pursued* were not published until 1777, three years after Tucker's death.

2 Associationist psychology

Like several other philosophers in the British empiricist tradition (notably David Hume), Tucker sought to explain the workings of the mind in terms of the principles of association that cause one idea to follow upon another. Among the associationists, Tucker makes explicit what some others seem to take as an unstated assumption: that if the flow of our ideas is entirely determined by certain principles of association, then the understanding has no role to play save that of a passive receptacle for ideas that flow through it according to laws of their own.

Our ideas combine with one another in either of two ways - by composition, in which several ideas 'melt together' to form a complex idea, and by association proper, in which ideas 'appear in couples strongly adhering to each other, but not blended' ([1777] 1977, vol. 1: 221). Ideas that are related through association can link together severally to form 'trains', in which a first idea couples with a second, which couples with a third, and so on.

After ideas become associated in a 'train', some of them may drop out, so that the earlier elements of the train come to associate directly with the later ones by means of 'translation'. When we first see a proof of a mathematical theorem, the theorem, the steps of the proof, and the certainty that we attach to each of these steps will associate with one another to form a train. Yet later we may recall only the theorem itself and the certainty that we once associated with the proof.

Tucker takes this process of translation to be the explanation for a variety of psychological phenomena, including (for example) our sympathy with the moods of others. As children, we soon learn to associate our own happiness with the actions of others, and to associate their actions with their moods - they may play with us when they are happy or ignore us when they are sad. Eventually, we come simply to associate our own pleasure or displeasure with their happy or unhappy moods - without any intervening link of action.

3 Moral and religious philosophy

Tucker says of the will (the active element of the mind) that 'all her motions depend upon motives, thrown upon her from external objects, or conveyed by the channels of experience, education, and example, or procured by her own cares and industry, whereto she was instigated by former motives' ([1777] 1977, vol. 4: 302). The 'active ingredient' in all our motives, however we might describe their details, is the prospect of our own satisfaction. (Tucker understood 'satisfaction' to be a more general term than pleasure, combining the presence of any desirable feelings with the avoidance of any undesirable feelings.) And 'the summum bonum… happiness… is the aggregate of satisfactions' ([1777] 1977, vol. 2: 233). Thus we are absolutely determined to seek our own happiness. But

Tucker's is a soft determinism that is compatible with free will, since 'freewill needs no compulsive force to keep her steady, for she communicates, by antecedent and external causes giving birth to her motives, with the fountain [God's design] whence all the other streams derive' ([1777] 1977, vol. 4: 303).

According to Tucker, 'rectitude hath not a substantiality or distinct essence of its own, but subsists in the relation to happiness, those actions being right which upon every occasion tend most effectually to happiness' ([1777] 1977, vol. 7: 151). And in this context, Tucker understands happiness to encompass the aggregate of satisfaction for all God's creatures. Thus he anticipates the later utilitarians William Paley and Jeremy Bentham not only in asserting that the greatest total happiness is the greatest good, but also in proposing a consequentialist morality in which the good is prior to the right (see Utilitarianism).

So we are absolutely determined to pursue our own happiness, yet moral rectitude lies in the maximal happiness of all. But according to Tucker there is no difficulty here: our self-interested motivation and moral rectitude are congruent; for God has arranged that each of us shall achieve our greatest happiness through the greatest happiness of all.

In order to establish the existence of God and gain insight into God's attributes, Tucker employs an extended argument that combines elements of the first-cause argument with elements of the argument from design (see God, Arguments for the Existence of §§1, 4-5). (At one point in this argument Tucker makes use of the clock and clockmaker analogy that William Paley would later popularize.) Tucker's God is omnipresent (existing necessarily, thus existing everywhere and for all time), omnipotent (powerful enough to be the cause of everything), and omniscient (intelligent enough to plan a universe).

Among the attributes of the creator which are most important to Tucker's moral philosophy are two manifestations of God's goodness: God's providence and God's equity. Tucker proposes that the workings of nature give evidence of the providence of a creator who aims at the happiness of everyone. Tucker also argues that because of 'the wants and weaknesses of human nature' ([1777] 1977, vol. 3: 278) we humans are partial to those from whose good opinion we think we may benefit, while God wants no benefit that any human being can provide. So God must be impartial.

Thus the creator aims at our happiness, and the creator also plays no favourites - each of us will receive an equal measure of happiness over eternity. (Tucker rejects the notion of eternal punishment for the wicked.) For that reason, if we seek to advance our own satisfaction at the expense of others, we know that any short-term advantage we may gain will ultimately be lost - either in this world or in the next. And if we choose to sacrifice our own satisfaction to promote the general good, we know that God will compensate us fully in the end.

Now it may seem that on Tucker's account, we will come out no better if we do good than if we do evil. It may not pay to do wrong, but does it pay to do right? Tucker argues that when we promote the general good, we increase the store of happiness that is available to us all, so that every benevolent act will enhance the 'profit to the common stock in partnership' ([1777] 1977, vol. 4: 502). Thus 'whoever adds to the happiness of another, adds thereby to his own' ([1777] 1977, vol. 4: 500).

4 Influences

Throughout *The Light of Nature Pursued* Tucker repeatedly acknowledges his debts to John Locke, but his other influences are hard to trace. He often mentions David Hartley (whose associationist psychology probably inspired Tucker's own) and George Berkeley, but both of these thinkers are usually cited in criticism. Tucker undoubtedly owes a debt to John Gay, but never refers to him by name; perhaps Gay's influence on Tucker came chiefly through Hartley. And Tucker may have been completely ignorant of his most famous contemporary, David Hume. Even where the two thinkers' ideas seem most similar, as in their belief in soft determinism and their associationist accounts of sympathy, they diverge in their arguments and in the details of their views.

Tucker's influence on the utilitarians who followed him, particularly William Paley, is powerful and direct. In the preface to his *Principles of Moral and Political Philosophy*, Paley says:

> There is, however, one work to which I owe so much that it would be ungrateful not to confess the obligation. I mean the writings of the late Abraham Tucker…. I have found in this writer more original thinking and observation, upon the several subjects that he has taken in hand, than in any other, not to say, than in all others

put together.

Turing machines

Turing machines are abstract computing devices, named after Alan Mathison Turing. A Turing machine operates on a potentially infinite tape uniformly divided into squares, and is capable of entering only a finite number of distinct internal configurations. Each square may contain a symbol from a finite alphabet. The machine can scan one square at a time and perform, depending on the content of the scanned square and its own internal configuration, one of the following operations: print or erase a symbol on the scanned square or move on to scan either one of the immediately adjacent squares. These elementary operations are possibly accompanied by a change of internal configuration. Turing argued that the class of functions calculable by means of an algorithmic procedure (a mechanical, stepwise, deterministic procedure) is to be identified with the class of functions computable by Turing machines. The epistemological significance of Turing machines and related mathematical results hinges upon this identification, which later became known as Turing's thesis; an equivalent claim, Church's thesis, had been advanced independently by Alonzo Church. Most crucially, mathematical results stating that certain functions cannot be computed by any Turing machine are interpreted, by Turing's thesis, as establishing absolute limitations of computing agents.

1 Human computors

In his seminal article of 1937, 'On Computable Numbers, With an Application to the *Entscheidungs-problem* [decision problem]', Alan Mathison Turing argued that a function is calculable by some algorithmic procedure if and only if it is computable by a Turing machine. The main claim in Turing's argument is that the behaviour of a human being carrying out an algorithmic procedure (adopting the terminology of Gandy (1988), a 'computor') is constrained by limitations of human memory and sensory capacities. It is appropriate to review briefly these restrictive conditions, for they are reflected in the mathematical definition of a Turing machine. (For a careful analysis of Turing's argument, see Sieg (1994); an analogue of Turing's argument for parallel computations by digital computers is given by Gandy (1980).)

Turing considered a 'one-dimensional' computing space formed by a potentially infinite tape uniformly divided into squares, in each of which at most one symbol may be written. What are the possible processes which can be carried out by a computor working on this computing space?

(1) The computor can write on the tape symbols from a fixed finite list (for example, letters of the alphabet). This restriction is argued for on the ground that if one allowed an infinity of symbols, then one would have symbols differing to an arbitrarily small extent (which, presumably, could not be unambiguously recognized or written down by the computor in view of sensory and memory limitations).
(2) The computor can observe squares on the tape. Limitations of human visual apparatus seem sufficient to justify the existence of a fixed finite bound *B* on the number of contiguous squares observable at any one moment.
(3) The computor can remember earlier stages of the computation and bring this information to bear on future behaviour. This memory consists in what Turing calls the computor's 'states of mind'. There is a fixed finite bound on the number of 'states of mind' which need be taken into account in a mechanical calculation. If one admitted the possibility of using infinitely many states of mind, Turing observes, some of them would be arbitrarily close and would be confused by the computor.
(4) The elementary actions the computor can perform consist of a change of either (a) observed squares or (b) the contents of some squares, possibly accompanied by a change of 'state of mind'. Any other operation of the computor can be viewed as a composition of these elementary actions. Furthermore, Turing assumes that (c) each of the newly observed squares must be within a bounded distance *L* of an immediately previously observed square, and that nothing will be lost by supposing that only the contents of observed squares can be changed.
(5) Which elementary action the computor is to undertake at a given moment depends only on what the computor currently sees and remembers. Thus, the observed squares and the 'state of mind' at any moment uniquely determine the action to be undertaken.

These restrictive conditions ensure that the computor's behaviour is fixed by a finite list of instructions: there are only finitely many different types of observable configurations of symbols (by (1) and (2)) and finitely many 'states of mind' (by (3)); to each pair formed by a 'state of mind' and type of observable configuration is uniquely

associated (by (5)) an elementary action (fixed by (4)).

2 (Universal) Turing machines

Turing claims that the behaviour of a computor satisfying the restrictive conditions above can be faithfully simulated by a machine organized as follows. The internal configurations $q_1, \ldots, q_n$ of the machine correspond to the states of mind $m_1, \ldots, m_n$ of the computor. The machine scans *B* squares corresponding to the *B* squares observed by the computor. In any of its actions, the machine can change a symbol on one of the scanned squares or shift attention to observe another configuration of symbols in such a way that condition (4)(c) is satisfied. The action undertaken at any moment by the machine, and its next internal configuration, are uniquely determined by the scanned symbols and the internal configuration at that moment. In turn, one can show that any computation of this machine can be carried out by a machine *M* endowed with a more elementary repertoire of actions, which provides an intuitive visualization of a Turing machine. This machine has a fixed finite number of internal configurations; it is capable of scanning only one square at a time (that is, $B = 1$); it may print or erase a symbol on the scanned square or else move on to scan either of the immediately adjacent squares (that is, $L = 1$).

To the machine *M* one can associate a function $f(x_1, \ldots, x_n)$ of *n* non-negative integers in the following way. Given an *n*-tuple $a_1, \ldots, a_n$, since the machine can print at least one symbol, say 1, the input $\langle a_1, \ldots, a_n \rangle$ can be represented on an otherwise blank tape by a sequence of $a_1 + 1$ consecutive 1's followed by a blank square followed by a sequence of $a_2 + 1$ consecutive 1's followed by a blank square… followed by a sequence of $a_n + 1$ consecutive 1's. The machine is to be started in a specific internal configuration, q_1, scanning the leftmost square containing a 1. The output number (if any), which is to be identified with $f(a_1, \ldots, a_n)$, is given by the number of 1's written on the tape to the right of the scanned square when (and if) the machine halts. These stipulations enable one to associate to *M* an *n*-ary *partial* (rather than total) function (that is, a function which may be undefined for some *n*-tuple of non-negative integers), because for some input the machine may fail to provide an output by not halting.

The initial stage of computation of *M* on the input $\langle a_1, \ldots, a_n \rangle$ has been described by giving (1) the tape content, (2) the machine's internal configuration, and (3) the scanned square. Each subsequent stage of the computation can be described by providing this information, which is called an 'instantaneous description' of the machine. Any computation which produces a final output can be described by a finite sequence of instantaneous descriptions.

The essential features of this type of machine can be captured by precise mathematical definitions. Let us consider the list of symbols $S_0, S_1, S_2, \ldots,$ $q_1, q_2, q_3, \ldots,$ *R* and *L*, and sequences of symbols from this list having one of the following forms:

(1) $q_i S_j S_k q_l$
(2) $q_i S_j R q_l$
(3) $q_i S_j L q_l$.

Sequences of this form are called 'quadruples'. Turing machines will be now defined (following Davis 1958) entirely in terms of quadruples, which can be interpreted as specifying the next action of a Turing machine when its internal configuration is q_i and the symbol it is scanning is S_j. Quadruple (1) indicates that S_j is to be replaced by S_k and the machine is to enter internal configuration q_l; quadruples (2) and (3) indicate that the machine is to shift one square to the right or to the left, respectively, and then enter internal configuration q_l. We stipulate that the symbol S_0 will serve as a blank; thus, replacing symbol S_j by S_0 amounts to erasing it.

Now a Turing machine is a finite, non-empty set of quadruples that contains no two quadruples with the same first two symbols. The latter condition guarantees the deterministic character of the machine operation, since no more than one instruction will be applicable at any given moment.

This definition identifies a Turing machine with a finite table of instructions in a certain normal form. Equally rigorous definitions can be given for the notions of instantaneous description and computation, as well as for the Turing computable functions, that is, the class of partial functions that Turing machines can compute (see Davis 1958: ch. 1). A basic result of computability theory is the extensional equivalence between this class of functions and the partial recursive functions. Analogous results have been obtained for classes of functions defined in terms of other algorithmic processes (Markov algorithms, lambda-calculi, Post's production systems, Kleene's

equational calculus, and so on; see Church's thesis; Computability theory).

One can define an algorithmic one-one correspondence of the members of the class of Turing machines with the set of all non-negative integers. This fact entails that there is an algorithm (and, by Turing's thesis, a Turing machine) enabling one to retrieve, given any integer *x*, the Turing machine indexed by *x* and, conversely, given any Turing machine, the integer associated with it (see Rogers 1958). This mapping yields an enumeration $M_0, M_1, M_2, \ldots$ of the class of Turing machines. Correspondingly, we shall indicate by f_x the partial function computable by M_x.

Under any such enumeration, there is a number *u* such that for any numbers *x* and *y*, the machine M_u computes the following binary function:

$$f_u(x, y) = \begin{cases} f_x(y) & \text{if } f_x(y) \text{ is defined} \\ \text{undefined} & \text{otherwise.} \end{cases}$$

Thus, the machine M_u can be employed to compute any unary Turing computable function. Furthermore, M_u can also compute the *n*-ary Turing computable functions, provided one codes any *n*-tuple $\langle y_1, \ldots, y_n \rangle$ of input numbers by means of a non-negative integer. Again, this coding can be given by means of Turing computable functions (see Davis 1958: ch. 4). In view of these properties, M_u is called a universal Turing machine. A universal Turing machine is explicitly described in Turing (1937).

3 The horizon of computability (and beyond)

There are number-theoretic functions which cannot be computed by any Turing machine. The mere existence of such functions follows from the fact that the class of Turing computable functions is denumerable (it can be put into a one-one correspondence with the non-negative integers) whereas, by Cantor's theorem (see Cantor, G.), there are indenumerably many number-theoretic functions.

Specific examples of non-computable functions were provided by Turing in his 1937 paper. Consider the so-called 'halting problem': is there a Turing machine capable of deciding for arbitrary *x* and *y* whether the Turing machine M_x will eventually halt after being started on input *y*? In other words, is the total number-theoretic function

$$h(x, y) = \begin{cases} 1 & \text{if } f_x(y) \text{ is defined} \\ 0 & \text{otherwise} \end{cases}$$

a Turing computable function? The answer to this question is negative: the function $h(x, y)$ is not Turing computable, and the halting problem is said to be unsolvable. Turing used the unsolvability of the halting problem to establish a negative solution to Hilbert's *Entscheidungsproblem* [decision problem] (see Church's theorem and the decision problem; Hilbert's programme and formalism).

The unsolvability of the halting problem implies that the behaviour of some Turing machines cannot be completely predicted by any Turing machine. An example of such 'unpredictable' machines is just the universal Turing machine M_u. The existence of a Turing machine capable of determining, for every *x* and *y*, whether the machine M_u will eventually halt when started on input $\langle x, y \rangle$ conflicts with the negative solution to the halting problem.

The import of this and other 'negative' results concerning Turing machines crucially hinges upon Turing's thesis. Indeed, if a function cannot be computed by a Turing machine then, by Turing's thesis, one can infer that there is no algorithm enabling one to calculate the values of this function. In particular, no algorithmic procedure can enable one to answer, for each *x* and *y*, all questions of the form 'Does M_x halt on *y*?' or, equivalently, 'Does *x* belong to the set K_y formed by the numbers *z* such that $f_z(y)$ is defined?'.

Suppose we are provided with some unspecified means - an oracle, as it were - for solving problems of the form 'Does *x* belong to *X*?', where *X* is a set of non-negative integers. One may then define a new class of machines, which one may call *O*-machines, suitably extending the definition of Turing machine so as to allow for quadruples of the form

(4) $q_i S_j q_k q_l$,

and associating to each *O*-machine a specific set *X* of non-negative integers. An *O*-machine in internal configuration q_i which is scanning symbol S_j may be interpreted as asking the oracle: 'Does the number *x* of occurrences of 1 on my tape at this moment belong to *X*?' If the answer is 'yes' then the *O*-machine changes its internal configuration to q_k; if the answer is 'no' then the *O*-machine changes its internal configuration to q_l (see Davis 1958: ch. 1). The function computable by an *O*-machine is said to be computable in the set *X* associated with that machine.

A class of functions computable in a set *X* may include functions that are not Turing computable. Furthermore, given a set *X*, one can prove the existence of functions that are not computable in *X*, that is, functions which cannot be computed by *O*-machines having access to an oracle capable of deciding membership of the set *X*. Results of this kind are central to the theory of the degrees of unsolvability, which introduces a hierarchy of classes of unsolvable problems.

One may also distinguish between classes of solvable problems, in terms of the amount of resources a computing machine may need for their solution. Among the various, equivalent models that are available, the model of computation commonly chosen to estimate these resources is that of the Turing machine (see Complexity, computational).

The notion of (universal) Turing machine also plays a prominent role in philosophical discussions of the mind-machine problem. Theoretical limitations of (universal) Turing machines have been appealed to in arguments purporting to show that the human mind is not subject to analogous limitations. Turing (1950) employed this notion in order to circumscribe the class of devices that are admitted to compete with human beings in his test for intelligent behaviour. More recently, (universal) Turing machines have been used to isolate distinguishing features of the notion of computational explanation in cognitive science, as well as heuristic ideas underlying research programmes in artificial intelligence (see, for example, Newell and Simon 1976).

Turing reducibility and Turing degrees

A reducibility is a relation of comparative computational complexity (which can be made precise in various non-equivalent ways) between mathematical objects of appropriate sorts. Much of recursion theory concerns such relations, initially between sets of natural numbers (in so-called classical recursion theory), but later between sets of other sorts (in so-called generalized recursion theory). This article considers only the classical setting. Also Turing first defined such a relation, now called Turing- (or just T-) reducibility; probably most logicians regard it as the most important such relation. Turing- (or T-) degrees are the units of computational complexity when comparative complexity is taken to be T-reducibility.

1 Usage and notation

ω = the set of all natural numbers; a real is a subset of ω. For sets A, B: $A \cup B = \{x : x \in A \text{ or } x \in B\}$; $A \times B = \{< x, y >: x \in X, y \in Y\}$; for $n \in \omega$, $n \neq 0$: $A^n = A \times \ldots \times A$ (taking *A* *n*-times). For a function φ: $\mathrm{dom}(\varphi)$ = the domain of φ; φ is a particle function on ω^n iff $\mathrm{dom}(\varphi) \subseteq \omega^{\mathrm{n}}$; such a function is total iff its domain is ω^n. In this article a partial function will be partial on ω^n for some $n \in \omega$; φ is total iff $\mathrm{dom}(\varphi) = \omega^n$. (So a total function on ω^n is also partial - an unfortunate, but standard, usage.) For a real *X*, χ_X, is *X*'s characteristic function: $\chi_X(x) = 1$ if $x \in X$; $\chi_X(x) = 0$ if $x \notin X$.

2 Informal characterization of T-reducibility

For reals *X* and *Y*: *X* is reducible to *Y* iff *Y* is at least as computationally complex (in a sense whose specification determines the reducibility relation) as *X* is, that is, given any $n \in \omega$ we could answer the question '$n \in x$?' by means that are in some sense computational except (perhaps) for using (subject to various possible constraints) answers to membership-questions about *Y*. For T-reducibility, we require computation to be effective and impose no restraints. A relativized algorithm consists of instructions like an 'absolute' algorithm (see Computability theory) except that they may tell one to 'ask a question of an oracle', one of the form 'what about *y*?', where *y* can be any natural number given to the oracle as a numeral; running the algorithm relative to *Y*, in a finite time the oracle says 'yes' if $y \in Y$, and 'no' otherwise. Suppose *A* is such a relativized algorithm, and we have an oracle for the real *Y* and infinite amount of time. Were we to apply *A* to a given input, we would grind along following *A* as we would an 'absolute' algorithm, except that from time to time *A* might specify a natural number (in some sort of numeral form) for us to ask the oracle about; the oracle would answer; we would grind on following *A*, exactly what *A* requires us to do being 'mechanically' determined by the answers the oracle gave to this and previous queries; eventually *A* might tell us to stop, delivering an output; *A* also might leave us computing forever. The oracle is oracular in that we do not trouble ourselves about how it comes up with its answers; going from a query of the oracle to its answer is a non-effective step in an otherwise effective computation. Now we will introduce some 'informal' definitions.

(I) A partial function φ on ω is computed by an algorithm *A* relative to a real *Y* iff for any $x \in \omega$, were we to run *A* on input *x* using an oracle for *Y*: if $x \in \mathrm{dom}(\varphi)$ the computation would halt giving the value $\varphi(x)$; if $x \notin \mathrm{dom}(\varphi)$ the computation would not halt. φ is computable relative to *Y* iff φ is computed by some such *A* relative to *Y*. *X* is decidable relative to *Y* iff χ_X is computable relative to *y* (that is, for some *A* for any $\chi \in \omega$, were we to run *A* on input *x* using an oracle for *Y*, the computation would eventually halt with a correct answer (1 = 'yes', 0 = 'no') to the question '$x \in X$?'. *X* is recursively enumerable relative to *Y* iff *X* is the range of a function that is total on ω and computable relative to *Y*.

3 Two rigorous definitions

One way to replace these informal definitions by rigorous definitions uses the notion of an oracle machine (that is, a relativized Turing machine (see Turing machines)), credited by Rogers (1967) to M. Davis. Fix a finite set ALPH (an alphabet) whose members we will call symbols, say with $0 (= \mathrm{blank}), 1, 2 \in \mathrm{ALPH}$; without mathematical loss, we could suppose that $\mathrm{ALPH} = \{0, 1, 2\}$. Recall the three usual rule-schemata defining being a Turing-machine table (for a single tape infinite in both directions and with '0' meaning 'blank') relative to ALPH and to a set STATE of internal states. Add to them this fourth schema (Query): for *y* = the number of occurrences of 1 on the tape at the moment, if in state *q* then: if the oracle says 'yes' to *y* then change to state q'; if it says 'no'

change the state q''. (By using occurrences of 2 rather than 1, the device can record and preserve results of previous steps while 'asking the oracle a question', insulating this record from the question asked.)

Pick $L, R \notin \mathrm{ALPH}, \mathrm{ACT} = \mathrm{ALPH} \cup \{L, R\}$. Represent any Turing-machine rule by a quadruple of the form $< q, s, a, q' >$ for $q \in \mathrm{STATE}, \mathrm{s} \in \mathrm{ALPH}, \mathrm{a} \in \mathrm{ACT}, \mathrm{q}' \in \mathrm{STATE}$, with this understanding: if $a \in \mathrm{ALPH}$ the instruction says 'Erase the cell and write *a*'; *L* and *R* represent 'Move the tape one cell to the left (that is, the head one cell to the right)' and 'Move the tape one cell to the right', respectively. Any rule of form (Query) can be represented by a quadruple $< q, s, a, q'q'' >$for $q, q', q'' \in \mathrm{STATE}, \mathrm{s} \in \mathrm{ALPH}$.

Let an oracle-machine table on $<< \mathrm{ALPH}, \mathrm{STATE} >$ be a function from $\mathrm{STATE} \times \mathrm{ALPH}$ into $(\mathrm{ACT} \cup \mathrm{STATE}) \times \mathrm{STATE}$. Identifying a function *f* with the set of ordered pairs of the form $< x, f(x) >$, and identifying an ordered pair of the form $<< a, b >, < cd >>$ with $< a, b, c, d >$, such a table is a set of quadruples coding instructions. For mathematical purposes, an oracle machine is an ordered pair $M =< T, q_0 >$ for *T* an oracle-machine table and $q_0 \in \mathrm{STATE}$; q_0 is *M*'s initial state. Given a tape with cells in any condition, a particular cell on that tape, and a real *Y*, if each query of the oracle is true to *Y* (that is, if the device is in state *q* reading *s*, *y* is as above, and $T(< q, s >) =< q', q'' >$, then the machine goes into state q' if $y \in Y$, and goes into state q'' otherwise), an oracle machine *M* carries out a uniquely determined succession of operations starting in state q_0 with its head on that chosen cell, one which may or may not terminate in a finite number of steps; this is its computation (also known as its run) relative to *Y*. The definition of an oracle machine does not involve a particular value for '*Y*': a given oracle machine *M* with a given input can run with any real *Y*, perhaps producing different computations for different reals. Also , talk of tapes and devices is heuristic, replaceable by an austere but tedious definition of the computation *M* carries out input *x* using *Y*.

(II) We associate with each such *M* and *Y* a partial function φ on ω as follows: represent a natural number *x* as input by string of $x + 1$ consecutive occurrences of 1 on the tape with all other cells blank; adding 1 distinguishes input 0 from starting with a blank tape. Start *M* in state q_0 reading the leftmost cell containing a 1; as output take the total number of occurrences of 1 appearing anywhere on the tape when and if the machine stops; thus $\varphi(x) =$ that total number of 1s; $x \in \mathrm{dom}(\varphi)$ iff *M* eventually halts when run with input *x*; if *M* does not halt, $x \notin \mathrm{dom}(\varphi)$ and $\varphi(x)$ does not exist (as mathematicians say, ' $\varphi(x)$ is undefined'). This φ is the partial function computed by *M* using *Y*. φ is T-computable from *Y* iff φ is computed by some oracle machine using *Y*. *X* is T-reducible to *Y* (in symbols $X \leq_T Y$) iff χ_X is T-computable from *Y*.

For $\mathrm{ALPH} = \{0, 1, 2\}$, represent the possible 'actions' by natural numbers: $i \leq 2$ for 'Erase the cell and write *i*'; 3 for *L*; 4 for *R*; represent the internal states as natural numbers greater than 4. Represent (or better, define) a machine-table as a function from a finite subset of $\omega \times \{0, 1, 2\}$ into a finite subset of $\omega \times \omega$; such a function can then be represented by a single natural number. An oracle machine *M* can be coded by a single natural number, *M*'s Gödel-number (see Gödel's theorems). For *e* = *M*'s Gödel-number, let φ^e_Y (alternative notation: $\{e\}^Y$) be the partial function *M* computes using *Y*.

(III) Turing himself did not use the notion of an oracle machine in his original definition of T-reducibility; rather he defined the class of partial functions (each on ω^n for any $n \in \omega$) recursive in a real *Y* (also known as the class of functions partial recursive in *Y*) to be the least class $\underline{C}$ meeting these conditions: (1) all initial functions belong to $\underline{C}$; these are successor, the function mapping each ω^n into $\{0\}$, and all projections (that is, functions of the form $f(x_1, \ldots, x_n) = x_i$ for some *i*, $1 \leq i \leq n$); (2) $\chi_Y \in \underline{C}$; (3) $\underline{C}$ is closed under composition, primitive recursion and minimization. A real *X* is recursive in *Y* iff χ_X is.

It is tedious but not hard to prove that this class is exactly the class of partial functions T-computable from *Y*. Thus *X* is recursive in *Y* iff *X* is T-reducible to *Y*. In fact, each of the various ways of defining being a recursive function extends naturally to a definition of being a function recursive in an arbitrary real *Y*. Some regard the coextensiveness of (II), (III), and those other definitions, as evidence that they all rigorously define what (I) informally defines, that is, as evidence for the relativized version of Church's thesis: a function is computable relative to *Y* iff it is T-computable relative to *Y* (see Church's thesis).

4 More definitions and facts

Let $X <_T Y$ iff $X \leq_T Y$ and not $Y \leq_T X$; *X* and *Y* are T-equivalent (in symbols $X \equiv_T Y$) iff $X \leq_T Y$ and

$Y \leq_T X$. As the notation suggests: $<_T$ is a reflexive transitive relation; $\equiv_T$ is an equivalence relation. We could prove these facts from the mathematical definition of (II) or (III); but it is easier to work informally.

Sample proof Let A and B be algorithms computing χ_X and χ_Y relative to *Y* and *Z* respectively. Consider this algorithm: given any *x*, run *A* on *X*; whenever A tells us to ask the oracle for *Y* about a *y*, run B on *y*, using the oracle for *Z*; eventually such a run of B halts; if it yields 1 or 0 take that as a 'yes' or 'no' respectively from an oracle for *Y*. A halts on an input if responses to its queries of an oracle are true to *Y*; a run of B using an oracle for *Z* does deliver the truth about *Y* (since it computes χ_Y); so this process halts, yielding $\chi_X(x)$, and it uses an oracle for Z (rather than *Y*, unless $Y = Z$). Thus $\leq T$ is transitive. (One of recursion theory's advantages is that we can almost always work in this informal way.)

For a real *X* let $\deg(x) = \{Y{:}\, X \equiv_T Y\}$. Let *a* be a T-degree iff $a = \deg(\mathrm{x})$ for some real *X*; $\mathcal{D}$ = the set of T-degrees. For $a, b \in \mathcal{D}$ let $a \leq b$ iff for some $X \in a, Y \in b, X \leq_T Y$. Note that if $a \leq b$ then for any $X \in a, Y \in b{:}\, X \leq_T Y$. The relation $\leq$ is partial ordering, that is, it is reflexive , transitive, and antisymmetric (that is, if $a \leq b$ and $b \leq a$ then $a = b$). Let 0 = the set of recursive reals. For *X*, $Y \in 0{:}\, X \equiv_T Y$; for any real *Z* if $Z \leq_T X$ then $Z \in 0$; thus $0 \in \mathcal{D}$. T-degrees are sometimes called 'degrees of unsolvability', rather misleading since one of them, 0, represents solvability (= recursiveness). For any real *Y* and any $X \in 0, X \leq_T Y$; thus 0 is the least T-degree under this (the standard) ordering. Study of the algebraic properties of the structure $<< \mathcal{D}, \leq>$ is a major component of recursion theory. One basic fact is that the partial ordering $\leq$ is very partial; for $a, b \in \mathcal{D}$, *a* and *b* are incomparable iff neither $a \leq b$ nor $b \leq a$; each T-degree is incomparable with continuum-many other T-degrees - as many as there are reals.

Let a degree be recursively enumberable (hereafter r.e.) iff it contains an r.e. real. Recursive reals are r.e.; so 0 is r.e. Let $K^X = \{x{:}\, \varphi_x^X(x) \text{ is defined}\}$. In 1944 E. Post gave the first example of a non-recursive r.e. set: for $K = K^{\{\}}$ for {} = the empty set; so deg(*K*) is another r.e. degree. He went on to pose 'Post's problem': are there other r.e. T-degrees? In 1956 R. Friedberg and A. Muchnik independently proved that there are others; some consider this the first deep result in degree theory. (See Friedberg 1957 or any of the textbooks referred to below.) The study of r.e. degrees is a flourishing corner of recursion theory.

The jump function on the reals assigns each real *X* to K^X. The effective version of Cantor's diagonal argument for the unaccountability of the set of reals (see Cantor's theorem) shows that $K^X \leq_T X$; since $X \leq_T K^X, X \leq_T K^X$. If $X \equiv_T Y$ then $K^X \equiv_T K^Y$; so it makes sense to define the jump function on the T-degrees: the jump of *a* (usually written a') is the T-degree of K^X for some (thus any) $X \in a$. Thus $a < a'$, showing the jump for degrees is a natural uniform way of transforming a T-degree into a more complex one. Obviously jumping iterates any finite number of times, yielding degrees of increasingly complex sets; in fact, it iterates through the so-called constructibly countable ordinals (see Hodes 1980), a matter closely connected to Gödel's constructible hierarchy (see The constructible universe).

A sentence in a formal language can be effectively coded as a natural number by 'Gödel numbering' (seeGödel's theorems); so a set of sentences, for example, a theory (in the logician's sense (see Model theory)), can be coded as a real; so its complexity can be identified with the T-degree of that real. Examples are: the theory of a dense linear ordering without endpoints has degree 0; the set of validities of first-order logic is r.e. and so has degree $0'$; ditto for the set of theorems of any axiomatizable theory in a countable language; the set of truths of first-order arithmetic has degree = 0^ω = the result of jumping 0^ω-times.

S. Simpson (1977) proved that the first-order theory of $< \mathcal{D}, \leq,' >$ (that is, the set of true first-order sentences based on a two-place predicate for $\leq$, a one-place function-constant for the jump, and 'first-order logic' with variables ranging over $\mathcal{D}$) was very complicated - of the same T-degree as the set of truths of second-order arithmetic. In 1990 B. Cooper announced a proof (still unpublished at the end of 1993) that the jump-function on $\mathcal{D}$ is first-order definable over $< \mathcal{D}, \leq>$, that is, there is a formula $F(x, y)$ with exactly free variables *x* and *y*, based on a two place predicate for $\leq$ and 'predicate logic', so that with quantifiers ranging over $\mathcal{D}$: for any $a, b \in \mathcal{D}$ $F(a, b)$ is true iff $b = a'$. With Simpson's theorem, this showed that the first-order theory of $< \mathcal{D}, \leq>$ is as complex as the truth-set of second-order arithmetic. Analysis of T-degree of the truth-set have been carried out for many other kinds of structures, including various pieces of $< \mathcal{D}, \leq>$.

Turing, Alan Mathison (1912-54)

Alan Turing was a mathematical logician who made fundamental contributions to the theory of computation. He developed the concept of an abstract computing device (a 'Turing machine') which precisely characterizes the concept of computation, and provided the basis for the practical development of electronic digital computers beginning in the 1940s. He demonstrated both the scope and limitations of computation, proving that some mathematical functions are not computable in principle by such machines.

Turing believed that human behaviour might be understood in terms of computation, and his views inspired contemporary computational theories of mind. He proposed a comparative test for machine intelligence, the 'Turing test', in which a human interrogator tries to distinguish a computer from a human by interacting with them only over a teletypewriter. Although the validity of the Turing test is controversial, the test and modifications of it remain influential measures for evaluating artificial intelligence.

1 Life

Turing was born in London. He was educated at King's College, Cambridge, where he began work in mathematical logic, soon writing his most brilliant article 'On Computable Numbers with an Application to the *Entscheidungsproblem*'. The German '*Entscheidungsproblem*' refers to David Hilbert's question whether mathematics is *decidable*, that is, whether there is for any mathematical assertion a definite procedure which will determine whether or not the assertion is true. Turing's work, along with contemporary work of Kurt Gödel and Alonzo Church, demonstrated the impossibility of such a general decision procedure. Moreover, his work on computable numbers and universal computing machines provided the conceptual foundation for the development of the modern computer.

During the Second World War Turing helped to design special computing equipment to decipher the German 'enigma' codes. Afterwards he led efforts to design some of the earliest computers, including the Automatic Computing Engine (ACE) in 1945 and the Manchester Automatic Digital Machine (MADAM) in 1948. Turing was prosecuted for his homosexuality in 1952. He died at the peak of his intellectual powers, an apparent suicide.

2 Turing machines and minds

Turing machines are highly idealized 'machines' (properly regarded as abstract objects that may or may not be realized in any physical material) that consist of a potentially infinite tape, divided into individual cells, on which the machine can read and write discrete symbols, and a set of state descriptions which specify what the machine is to do when, in a particular state, it reads a particular symbol: it can leave it alone, erase it, write a new symbol in its place, move one cell to the left or right, and enter a new or the same state (see Turing machines). Turing showed how such machines could compute many ordinary arithmetical functions, and conjectured that anything that could be intuitively regarded as computable at all could be computed by such a machine (what has become known as the 'Church-Turing thesis'; see Church's thesis).

A particularly important Turing machine is the universal Turing machine, which serves as the prototype of the standard 'computer': when its tape is supplied with a coded description of any Turing machine (or 'program') and some input for that machine, it computes precisely what *that* machine *would* compute when supplied with that input.

The concept of a Turing machine furnishes a theoretical foundation for much work in cognitive science and artificial intelligence, where the driving idea is that cognitive processes, and maybe all mental processes, are ultimately computational (see Artificial intelligence; Mind, computational theories of). Processes of perception, reasoning, and decision making, for example, are to be explained in terms of computations operating on the input to sense organs. A version of this computational approach to the mind is called 'Turing machine functionalism' (see Block 1980).

One of the philosophically most important consequences of Turing's proposal is that it provides a method of explaining overall mental activity in simple mechanical terms. It thereby meets a recurring worry about psychological theories; that they vacuously postulate an intelligent 'homunculus' to explain intelligent activity.

Rather than resorting to a master homunculus to explain the mind, a hierarchy of computational systems is postulated, each of which is made up of simpler computational systems, until finally there is nothing left but simple mechanical components whose operations can be understood purely in terms of physical causation.

3 The Turing test

Turing not only provided a rigorous account of computation in terms of Turing Machines, but also proposed a classic test for examining machine mentality. His test, the Turing test, is designed to examine the ability of computers to imitate humans. In the Turing test a human interrogator or 'judge' puts questions to two unseen subjects - one a computer and the other a human. The task of the interrogator is to determine, based on teletypewriter communication with the two unseen subjects, which is the computer and which is the human. The goal of the computer is to imitate a human, including the imitation of typical human strengths and weaknesses. To use Turing's own example, when the computer subject is asked to add 34,957 and 70,764, it does not respond immediately but waits about 30 seconds and then responds with 105,621 rather than the correct answer 105,721. Although Turing does not specify, it is reasonable to assume that the interrogator is allowed to ask many questions over an extended period of time. The computer passes the test if and only if the interrogator cannot distinguish (better than chance) between the computer and human responses.

The Turing test has a number of virtues as a scientific test. First, the test is conducted with blind impartiality. The interrogator in the test cannot judge the computer to be non-intelligent because of its appearance alone. The sophistication of the behaviour is the crucial variable, and linguistic behaviour in the test can be evaluated without subtle bias due to appearance (see Behaviourism, analytic). Second, the test is reproducible. If the computer really has intelligence, then it has a cluster of abilities that can be demonstrated over and over again.

The Turing test is, however, open to many criticisms.

(1) The *action* objection: the Turing test examines only linguistic behaviour, but intelligence and thinking must be evaluated in terms of bodily actions within real contexts, not merely through linguistic behaviour over a teletypewriter. A possible reply: actions of any kind can be *discussed* within the Turing test, and that is sufficient to establish intelligence. After all, a human who is largely paralysed but who has adequate linguistic capabilities can still demonstrate intelligence.

(2) The *jukebox* objection: because the test is finite, pre-selected answers could be entered for every possible question (see Block 1981), but surely merely accessing such a list should not be intelligence. A possible reply: this is not a practical option as the number of answers needed is astronomically high. In any remotely realistic test, the proper response at any given time depends on common knowledge of the real world which is constantly and unpredictably changing.

(3) The *syntax* objection: computers operate syntactically, not semantically, and can never understand what they produce even if the result passes the Turing test (see Searle 1980; Chinese room argument). A possible reply: although the computer's operations are defined purely syntactically (in terms of what the cursor reads and writes), this does not preclude the possibility that they possess causally efficacious semantic properties. A computer as a whole functioning system may possess semantics and hence be capable of understanding (see Language of thought).

(4) The *Barnum* objection: there have been *restricted* Turing tests (subject to limits of time, topic and style of question) that have been actually staged, and which a number of computer programs have passed (see Shieber 1994 for discussion). However, as Block (1981) points out, they only show what P.T. Barnum claimed: people are easy to fool. A possible reply: the restrictions on these tests have been too severe; it is very implausible that a computer that passed a fully *unrestricted* test, in which any topic could be discussed in any way for substantial amounts of time, could really lack intelligence.

The Turing test is often understood as providing necessary and sufficient conditions, an 'operational' definition, for computer thinking. Turing, himself, did not insist that the test be so interpreted. Indeed, on the contrary, Turing believed that a machine might fail the test, not due to a lack of intelligence, but due to a lack of the ability to imitate a human. The computer might add too quickly and give itself away. A weaker, inductive interpretation of the Turing test is more defensible. On the inductive interpretation the Turing test is not expected to provide

deductively conclusive evidence, but merely *scientific inductive* evidence for the hypothesis that computers have intelligence similar to humans. How good the evidence is depends on how well the computer does in the test. If a computer actually passed a full Turing Test, then the proponent of the Turing test would claim that good inductive evidence would exist to infer that the computer has intelligence similar to our own.

Turnbull, George (1698-1748)

George Turnbull was an early champion of the use of empirical methods in the moral sciences. Involved in contemporary religious debate, he favoured religious toleration and the use of rational argument in defence of Christian belief. He also made contributions to educational theory and practice.

Born in Alloa, Scotland, on 11 July 1698, George Turnbull studied at the University of Edinburgh, where he was an early member of the Rankenian Club. Like his fellow Rankenians, Turnbull was interested in contemporary religious debates, and in 1718 he tried to initiate a correspondence with the deist John Toland (1670-1722) (see Deism; Toland, J.). During the late 1710s he also composed a manuscript treatise on civil religion which remained unpublished because of the controversial nature of his argument in favour of religious toleration. After graduating with his MA from Edinburgh in April 1721, he became a regent at Marischal College, Aberdeen, and taught there until he resigned in 1727.

Although Turnbull had a chequered career in Aberdeen, he played a major part in the transformation of Marischal's philosophy curriculum. He helped to popularize the writings of the Third Earl of Shaftesbury, and he joined with other regents to promote the study of natural jurisprudence and history. Along with some of his colleagues, Turnbull expounded the political views of Old Whigs like Lord Molesworth (1656-1725), with whom he corresponded about education and religion. He also mobilized Newtonian natural philosophy in the service of religion, and developed a rational form of Christianity designed to counter the attacks of deists and atheists. But perhaps his most important contribution was his proposed methodological reformation of moral philosophy. Although he may have been indebted to his teachers at Edinburgh for the initial idea, Turnbull was the first Scottish moralist to advocate in print the use of the experimental method to investigate moral questions, and his advocacy of a scientistic approach to morals left a permanent mark on eighteenth-century Scottish philosophy, especially through the influence of his pupil Thomas Reid.

After such an auspicious start, Turnbull's subsequent career was something of a prolonged anticlimax. Following his departure from Aberdeen, he worked as a tutor to young aristocrats on the Grand Tour until he settled in London in the mid-1730s. During his travels he published two tracts on the rational basis of Christian belief (1731, 1732), and he addressed this topic again in 1740 in his most substantial publication, *The Principles of Moral Philosophy*. Turnbull here reiterated his call for the use of the experimental method in the moral sciences, and elaborated upon this theme in a dissertation appended to his translation of Heineccius' work on natural law (1741). 1740 also saw the appearance of his *Treatise on Ancient Painting*, wherein he expanded upon the basic elements of Shaftesbury's aesthetics in the context of a historical review of the development of painting and sculpture among the ancients. In addition, the *Treatise* considered the role of the fine arts in education, and issues of pedagogy were the primary focus of his last significant book, the *Observations upon Liberal Education* (1742), which despite its derivativeness makes a persuasive case for the structural unity of all branches of human learning. Turnbull's feverish literary activity points to his continuing search for settled employment and, having been ordained in 1739, he sought preferment in the Anglican Church. He was eventually rewarded with a minor position in Ireland, and he died in relative obscurity in the Hague on 31 January 1748.

Twardowski, Kazimierz (1866-1938)

Twardowski, one of the most distinguished of Brentano's students, became famous for his distinction between the content and object of presentations. Twardowski, after his appointment as a professor of philosophy at the University of Lwów (Lvov), considerably limited his own philosophical research for the sake of teaching activities. He set himself an ambitious task: to create a scientific philosophy in Poland. Twardowski fully realized his aim, giving the first step towards the so-called Lwów-Warsaw School, a group of philosophers working in analytic philosophy - in particular, logic, philosophy of science, and philosophy of language. In spite of his concentration on teaching, Twardowski also made remarkable contributions to philosophy after coming to Lwów.

1 Life and teaching activity

Kazimierz Twardowski was born in Vienna on 10 October 1866. He was educated in a famous Viennese secondary school, *Theresianum*. In 1885-9 he studied philosophy at Vienna University, mainly under Franz Brentano. He obtained his Ph.D. in 1892 for a thesis on the relation between ideas and perception in Descartes. Two years later Twardowski obtained his *Habilitation* on the basis of a dissertation on the content and object of presentations. Having *venia legendi*, Twardowski started lecturing at the University of Vienna as *Privatdozent*. In 1895 he was appointed Professor of Philosophy at the University of Lwów. Twardowski came to Lwów with the definite aim of establishing a scientific philosophical school in Poland. Indeed he subordinated all his academic activities to the realization of this goal, which he regarded as an important national duty; when Twardowski came to Lwów, Poland was still partitioned between Germany, Russia and the Austro-Hungarian Empire. Twardowski spent the rest of his life in Lwów, where he died on 11 February 1938.

The results of Twardowski's activities as a teacher were enormous. Almost all important Polish philosophers of the first half of the twentieth century were his students, in particular Kazimierz Ajdukiewicz, Tadeusz Kotarbiński, Stanisław Leśniewski, Jan Łukasiewicz and, briefly, Roman Ingarden. Twardowski's teaching activity gave rise to the Lwów-Warsaw School, the most important school in the history of Polish philosophy.

2 The conception of philosophy

Following Brentano, Twardowski embraced a conception of philosophy as a science based on descriptive psychology. For Twardowski, scientific philosophy should avoid hopeless general problems, like the question whether the world is material or spiritual, and concentrate on particular problems which might be properly analysed. Twardowski regarded most traditional philosophical questions, particularly in metaphysics, as matters of faith and worldview rather than proper science. He strongly insisted that philosophy must begin with careful and precise clarifications, because otherwise it is simply impossible to understand what is going on in philosophical questions and discussions. Thus, a clear statement of a given question is the first duty of philosophers. Twardowski's general metaphilosophical claims decisively favoured some philosophical fields, like logic, semantics (in the broad sense: that is, including syntax, semantics as a theory of reference, and pragmatics), epistemology, and philosophy of science. This is why his students undertook their basic research in those areas of philosophy.

3 The content-object distinction

Twardowski adopted the main theses of Brentano's descriptive psychology, in particular his conception of the psychic as essentially intentional and his distinction between mental acts and their objects. Twardowski's main contribution to the Brentanist philosophical tradition consists in his having added to the act-object distinction a third ingredient: the content. In his *Habilitation* dissertation Twardowski gave a detailed analysis of the content-object distinction in the case of presentations (see Intentionality).

Twardowski offers three direct arguments for introducing contents of presentations: (a) contents and objects cannot be identical, because true negative judgments which deny the existence of objects are based on presentations; their contents exist, their objects do not; (b) contents have properties which objects lack, and conversely objects have properties which contents lack; for example, redness as a property of an object cannot be attributed to the content of this object; (c) there are non-equivalent contents of presentations which refer to the same objects; for example, 'the city located at the site of Roman Juvavum', and 'the birthplace of Mozart'.

Twardowski observed that there is a close analogy between psychology and semantics. In particular, names and presentations are parallel, because names (a) make known acts of presentation which occur in the speaker, (b) arouse mental contents in the listener (for Twardowski, mental contents are meanings of names), (c) designate objects which are presented by meanings of names. This parallelism played a significant heuristic role in Twardowski's distinction. However, perhaps its more important function was that it led Twardowski to employ semantic analysis in descriptive psychology. Thus, Twardowski noted that when we use the expression 'a presented object', the adjective 'presented' may function as a determiner or as a modifier. This ambiguity is responsible for a confusion between contents and objects, in particular for the idealistic thesis that contents are genuine objects of our presentations. This observation led Twardowski to the realistic account of intentionality: our mental acts are usually directed to ordinary objects.

Twardowski extended his psychological and semantic analysis by important ontological considerations. Contrary to Bolzano, he defended the thesis that there are no objectless presentations. He also outlined a mereological theory of objects of presentations.

Twardowski's *Habilitation* dissertation had considerable historical significance. It influenced Meinong, in his general theory of objects, and Husserl's theory of intentionality. However, Husserl criticized Twardowski for psychologism and unclarities in the nature of content. Although the objection of psychologism was fully justified and recognized by Twardowski himself, Husserl's accusation that Twardowski fell into the picture theory of content is a misunderstanding.

4 Other contributions to philosophy

As already noted, Twardowski agreed that his account in his *Habilitation* dissertation was too psychologistic. Later he proposed an important distinction between actions and products. Twardowski begins by pointing out that there are characteristic pairs in which the first word is a verb (for example, sing, command) or a gerund (singing, commanding) and the second is a related noun (song, command). The first word refers to an action and the second to the product of that action. Products may be non-durable, for example the song which terminates when singing stops, or durable, for example the painting as a product of painting. Twardowski was mainly interested in durable psychophysical products. For Twardowski, such products express mental states and become their signs. In this sense, expressed mental states may be considered as meanings of the given signs. This scheme enables us to draw a distinction between logic and psychology. Psychology is primarily interested in actions, but logic in their durable products and their formal connections. Moreover, there is an obvious linkage between both fields, because meanings are generated by actions.

Twardowski strongly defended the view that there are no relative truths: if something is true, it is absolutely true. He argued that typical arguments for the existence of relative truths are based on simple confusions. For example, if one says that 'today it is raining' is an example of a relative truth, one forgets that this phrase expresses only an incomplete proposition. Once it is made complete (by indicating spatiotemporal coordinates), it becomes absolutely true. Also empirical hypotheses do not provide examples of relative truths. Twardowski points out that if we accept hypotheses as only probable, this means only that we do not know their actual logical values. If it turns out that a given hypothesis is at variance with fact, we consider it as false from the very beginning, and not as a proposition which changes its logical value.

Type/token distinction

The type/token distinction is related to that between universals and particulars. C.S. Peirce introduced the terms 'type' and 'token', and illustrated the distinction by pointing to two senses of 'word': in one, there is only one word 'the' in the English language; in the other, there are numerous words 'the' on the physical page you are now looking at. The latter are spatiotemporal objects composed of ink; they are said to be word tokens of the former, which is said to be the word type and is abstract. Phonemes, letters and sentences also come in types and tokens.

The distinction between 'type' and 'token', or something very like it, seems to be applicable beyond language to, for example, Beethoven's *Fifth Symphony* and performances of it, the grizzly bear and specimens of it, the Kentucky Derby and runnings of it, and the bubonic plague and outbreaks of it. The type/token distinction is important to linguistics, logic, aesthetics and philosophy of science. In philosophy of mind it is critical to distinguish types of events/states/processes from tokens of them, because those who identify mental events with physical events agree that every mental event token is a physical event token, but divide over whether mental event types, for example, pain, are identical to physical event types, for example, C-fibre stimulation (see Mind, identity theory of). Just what types are, whether they exist, whether they are 'present in' their tokens and whether all types have tokens are matters of controversy.

To see that we often refer to types, consider the grizzly bear. At one time its US range was most of the west and it numbered 10,000 in California alone. At the end of the twentieth century its range is Montana, Wyoming and Idaho, and it numbers fewer than 1,000. But no particular flesh and blood bear numbers 1,000 or once had a range comprising most of the western USA; if anything, it is a type which does. Similarly, Old Glory had twenty-nine stars in 1846 but fifty in 1996, whether or not any particular American flag underwent such a transformation; Old Glory is also a type.

This last example points to a related notion, that of an 'occurrence'. The stars on Old Glory number fifty; but fifty star *types* or fifty star *tokens*? In fact it cannot be either: not star types, because all the stars on the flag are of the same (five-pointed) type; nor star tokens, because tokens are concrete and the flag in question is abstract and cannot contain concrete parts. Old Glory contains fifty occurrences of the (five-pointed) star. Similarly, the letter '*x*' (the very same letter type) occurs three times in the formula (type) ' $(\forall x)(Fx \rightarrow Gx)$'. Thus the notion of an occurrence of '*x*' must not be confused with the notion of a token of '*x*' (although it often is so confused). The notion of 'an occurrence of *x* in *y*' involves not only *x* and *y*, but also how *x* is situated in *y*. If we think of a formula as a sequence, then the air of mystery over how the same identical thing can occur twice vanishes. Even concrete particulars can occur more than once (for example, the same person occurs twice in the sequence of New Jersey million dollar lottery winners).

Tokens are particulars. Are types universals? They are if having instances makes something a universal. But in many ordinary and theoretical contexts, terms which refer to types function not as predicates but as singular terms, in sentences that permit existential generalization. ('The grizzly bear ranged over most of the west' entails 'Something ranged over most of the west', for example.) As values of bound first-order variables, they meet a Quinean necessary condition for existence, and thus may also be viewed as particulars (see Ontological commitment §1).

Do types exist? If types are universals, then the debate over whether they exist goes back at least to Plato. Still, as the preceding paragraph noted, types seem to have an existential advantage over more traditional universals. (Quine held that expression types exist, though not more traditional universals (1987).) Nominalists who deny that there are any abstract objects argue that this is an illusion; that talk about types is just shorthand for talk about tokens. The matter cannot be resolved here, but it may be useful to examine one popular nominalistic account, namely, that every reference to a type (for example, 'The grizzly bear is ferocious') can be replaced without change of information by quantification over all tokens (for example, 'Every grizzly bear is ferocious'). One problem for this account is the existence of numerous counterexamples. 'The grizzly bear ranged over most of the west', for example, cannot be analysed as 'Every grizzly bear ranged over most of the west'. (Perhaps it can be analysed in some other 'type-free' way, but the point is that the nominalistic account under consideration cannot be the systematic one needed to eliminate all the many references to types which occur in our ordinary and

scientific talk.)

A second problem is created by the implication that all types have tokens. Peirce (1931-58) claimed they do, but many thinkers since have denied this. Chomsky (1957), for example, claimed that there are sentences that never have been or will be instantiated - infinitely many. A third problem arises when we try to find a replacement for even a simple true sentence about, say, the word ‘one’, given the myriad senses it has, and the myriad forms its tokens may take: printed in ink in any number of fonts and handwritings, raised in Braille, incised in marble, existing briefly as so many pixels of light on a computer screen, electronic strings of dots and dashes, smoke signals, hand signals, individual air disturbances produced by human vocal cords, electromagnetic pulses on phone lines, pronounced (and mispronounced) in countless ways in countless accents. Even an (appropriately surrounded) empty space can be a token of ‘one’. About the only thing all and only tokens of ‘one’ clearly have in common is being tokens of ‘one’ - the type, that is; if that word (type) does not exist, then they would seem to have nothing in common and hence no appropriate quantification could even be formulated.

Udayana (11th century)

*Perhaps the most important philosopher of the Nyāya school, Udayana authored several works in the eleventh century which brought to a close the long-standing debate between Nyāya and Buddhist philosophers. The realist Nyāya philosophers had argued for the existence of an enduring self (*ātman*), a thesis denied by their Buddhist opponents. Such was the importance of this disagreement that it pervaded all other areas of philosophical contention between them. In the Ātmatattvaviveka (On the Discrimination of the Reality of the Self), Udayana systematically clarified the connections between the* ātman *debate and many other areas of philosophical dispute, with the result that, in defending* ātman, *he also produced a masterly defence of Nyāya realism. Udayana is also credited with giving the definitive defence of theism in the Nyāyakusumāñjali (A Handful of Nyāya-Tree Flowers).*

Tradition has it that Udayana came from Mithila in north-east India, a centre of great learning, especially for the Nyāya school. His life is shrouded in mythical tales of his brilliance. There is no question, however, about his pre-eminent place in the evolution of Nyāya thought. Udayana was the last of the Nyāya philosophers to enjoy the stimulus of a powerful Buddhist opposition, for it was shortly after his death that Buddhism began to disappear from India. After Buddhism's demise, Nyāya thought became characterized by increasing subtlety of argument and a greater preoccupation with method than with content. Although Navya-Nyāya (New Nyāya), as the school in its later period is called, is usually said to date from the fourteenth century, the subtlety of Udayana's work is such that some critics regard him as its real source. Certainly Udayana's style and rigour look forward to Navya-Nyāya, but at the same time his work brings to fruition the arguments that traditional Nyāya philosophers had developed in their efforts to defeat the Buddhists. While no one would want to credit the demise of Buddhism in India to Udayana's polemics, the quality of the philosophical exchange between him and his Buddhist opponent, the monk Jñānaśrīmitra, represents one of the greatest achievements of Indian philosophy.

In the *Ātmatattvaviveka (On the Discrimination of the Reality of the Self)*, Udayana states that there are four main theses which the Buddhists give to refute the existence of *ātman* (Self): (1) all existent things are momentary; (2) there are no objects external to our judgments; (3) there is no difference between an object and its qualities; and (4) the *ātman* is not perceived. Apart from the last thesis, it can be seen that the Buddhist denial of *ātman* is a consequence of a more general argument about the nature of reality (see Momentariness, Buddhist doctrine of). Udayana concentrates his arguments against these general theses rather than arguing about *ātman* in particular, and it is this that gives the work its philosophical breadth and interest.

For example, the thesis of universal momentariness not only rules out the possibility of an enduring *ātman*, but is also the antithesis of Nyāya's realist view of the world and becomes a denial of the enduring existence of everything, from the *ātman* to the kitchen pot. Thus Udayana denies any concomitance between existence and momentariness and attacks the related notion of causal efficacy. It is only when causal efficacy is understood to mean the immediate production of an effect that the concomitance between existence and momentariness is established. Jñānaśrīmitra states that an enduring entity is incapable of causal efficacy and so lacks existence. The relationship between a dormant seed in the granary and a sprouting seed in the field is the locus for this debate. For the Buddhist argument to succeed, the nature of causal efficacy must be such that it creates a difference in identity between the nonsprouting granary seed and the sprouting field seed. Udayana argues for an interpretation of causal efficacy which allows for one and the same object to be causally efficacious at one time and not at another, thus allowing for the continuity of the granary seed with the field seed. He argues that to be causally potent does not mean that a cause must produce its effect immediately, but rather that it has the potential to do so given the presence of the right accessories - in the case of the seed, such things as sunshine and water. Udayana notes that we call seeds in the granary 'seeds' precisely because of their potential to produce sprouts. He charges that the Buddhists are not even entitled to call the seeds in the granary 'seeds' if, as they claim, those seeds are not responsible for the final production of sprouts. According to Udayana, the capacity or disposition of a seed to produce a sprout ultimately depends on the universal 'seedness' inhering in each individual seed. The presence of this universal along with the necessary accessories allows a nonproductive seed to become productive. The Buddhist position represents a lapse into chaos, where sprouts can be produced without seeds, and seeds are deprived of their very nature. Udayana's detailed critique of the Buddhist understanding of causality was accepted as definitive by later Nyāya philosophers (see Causation, Indian theories of §§5-6).

Although real universals were essential to Udayana’s attack on the Buddhist account of causality, and although he was a severe critic of Buddhist nominalism, he did recognize that not all general terms represent universals that have an independent reality (see Nominalism, Buddhist doctrine of §§1-2; Universals, Indian theories of §§2-3). Uddyotakara had distingushed real universals, such as ‘cowness’, from those constructed by us, such as the property of being a cook. In the *Kiraṇāvalī(Garland of Rays)*, Udayana contributed to the debate by giving a list of formal conditions which distinguish real universals (*jāti*) from those that are convenient devices of our own construction (*upādhi*). Some contemporary philosophers of language have noted an affinity between Udayana’s *jāti* and what are now called ‘natural kinds’.

Despite Udayana’s obvious flair for rigorous philosophical debate, he did not abandon the traditional soteriological concerns of philosophy. In the *Nyāyakusumāñjali (A Handful of Nyāya-Tree Flowers)*, he defends the theism of his school by developing a rational theology, using arguments that would be familiar to Western theologians. We infer the existence of God, for example, from our experience of order in the world, just as we infer the existence of a potter from the presence of a pot. For Udayana, the realism of the Nyāya school provided the most coherent support for *ātman* and, in a remarkable passage in the *Ātmatattvaviveka*, he places Nyāya at the pinnacle of philosophical thought. In accordance with the Nyāya system, he emphasizes that liberation cannot just be a matter of transcendental experience, but must incorporate correct philosophical knowledge.

List of works

A great deal of Udayana’s work remains to be translated from the Sanskrit. His works are listed below in chronological order. These are the Sanskrit texts unless indicated otherwise.

Udayana (11th century) *Lakṣaṇāvalī(The Garland of Definitions)*, ed.G. Jha, Darbhanga: Mithila Institute Series 13, 1963; trans. M. Tachikawa, in *The Structure of the World in Udayana's Realism*, Dordrecht: Reidel, 1981. (A manuscript on the categories of the Vaiśeṣika school.)

Udayana (11th century) *Lakṣaṇamāla (The Wreath of Definitions)*, ed. G. Jha, Darbhanga: Mithila Institute Series 14, 1964.(A manual on the categories of the Nyāya school.)

Udayana (11th century) *Ātmatattvaviveka (On the Discrimination of the Reality of the Self)*, ed. D. Sastri, Varanasi: Chowkhamba, 1940.(A comprehensive survey of the Buddhist arguments against the existence of the self or *ātman*. In countering these arguments, Udayana also gives a defence of the realism of the Nyāya school.)

Udayana (11th century) *Nyāyapariśiṣṭa (The Nyāya Appendix)*, ed. N.C. Vedantatirtha, Calcutta: Calcutta Sanskrit Series, 1938.(A commentary on the fifth chapter of the *Nyāyasūtra*, the foundational text of the Nyāya school.)

Udayana (11th century) *Nyāyavārttika-tātparyaṭīkā-pariśuddhi (An Exoneration of the Nyāyavārttika-tātparyaṭīkā)*, ed. L.S. Dravid and V.P. Dvivedin, Calcutta: Bibliotheca Indica, 1911; trans. in part in Jha, G., *The Nyāya-Sūtras of Gautama with the Bhāṣya of Vātsyāyana and the Vārtika of Uddyotakara*, Delhi: Motilal Banarsidass, 1984. (A partially extant work which continues with the tradition of building on previous subcommentaries on the *Nyāyasūtra*, in this case Vācaspati Miśra’s commentary, the *Nyāyavārttika-tātparyaṭīkā*, which is itself a commentary on Uddyotakara’s *Nyāyavārttika*.)

Udayana (11th century) *Nyāyakusumāñjali (A Handful of Nyāya-Tree Flowers)*, ed. L.S. Dravid and N.C. Vedantatirtha, Calcutta: Kashi Sanskrit Series, 1912; Books 1 and 2 trans. Ravitirtha, *Adyar Library Bulletin* 5 (1941), 6 (1942), 7 (1943), 10 (1946).(Considered by some to be Udayana’s greatest work, in which he gives a definitive defence of the Nyāya conception of God.)

Udayana (11th century) *Kiraṇāvalī(The Garland of Rays)*, ed. Sivachandra Sarvabhauma and N.C. Vedantatirtha, Calcutta: Bibliotheca Indica, 1956.(A commentary on Praśastapāda’s *Padārthadharmasaōgraha*, an early, foundational work on the Vaiśeṣika system. Portions of the *Kiraṇāvalī* are translated in Tachikawa 1981.)

Uddyotakara (6th century)

Uddyotakara, a philosopher of the Nyāya school, wrote the Nyāyavārttika, a lengthy commentary on the Nyāyasūtra. His most urgent task was to re-establish the authority of the Nyāya school in the face of extensive criticism from the great Buddhist logician Dignāga. Dignāga had been particularly critical of the logical work of Vātsyāyana, Uddyotakara's predecessor. In response, Uddyotakara incorporated Dignāga's logical work into the Nyāya school, and added his own interpretation. He was less receptive to Dignāga's other views, especially his account of perception and its relation to language.

Uddyotakara ('The Enlightener') was sometimes referred to as a Pāśupata teacher, indicating membership of a particular sect of devotees of Śiva. It is not therefore surprising to find in him a strong proponent of theism. Certainly since Vātsyāyana, Nyāya contained an element of theism inasmuch as God was recognized as a substantial Self distinct from other selves. Uddyotakara, however, gives a much fuller articulation of the Nyāya conception of God as creator, as omnipotent and as being beyond *dharma*. His arguments in support of such a God became an important aspect of the Nyāya tradition. Udayana's classic defence of theism, in his *Nyāyakusumāñjali (A Handful of Nyāya-Tree Flowers),* was the culmination of Uddyotakara's efforts in this vein.

Uddyotakara's importance for the Nyāya school, however, lies in his response to Dignāga. A skilled logician himself, he fully appreciated Dignāga's work. Dignāga had grasped the formal character of inference and had formulated three conditions under which the reason given for a thesis would result in a correct inference. Uddyotakara's acceptance of his opponent's analysis of logical inference was mitigated by his criticisms of its details. He demonstrated that Dignāga's three conditions actually mask sixteen possible ways in which the reason could be combined with the other members of the inference. Thus a more precise analysis would be needed to demarcate correct and incorrect inferences (see Inference, Indian theories of §§5-6).

In other areas Uddyotakara asserted his differences with Dignāga more vehemently. Unlike Nāgārjuna, Vātsyāyana's opponent, Dignāga offered a clearly articulated metaphysics in opposition to Nyāya realism. In his system there is a radical break between language and the world. The world is made up of unique momentary particulars (*svalakṣaṇas*) whose fleeting existence can be grasped only by perception. The judgments that we make about the world and express in language create a set of fictional categories, such as physical objects and universals, which are a result of our mental construction. Uddyotakara opposed this view by reaffirming and expanding Vātsyāyana's arguments for the perceptual basis of physical objects (see Vātsyāyana). He also initiated the Nyāya opposition to the Buddhist theory of meaning, known as *apohavāda*, which originated with Dignāga. Dignāga had avoided all commitment to any real basis for the terms of our language, such as universals, by proposing that words derive their meaning and usefulness on the basis of a common exclusion, rather than any set of properties held in common.

Since the *Nyāyasūtra* had given a definition of perception as being that which is not expressible, it might seem that Dignāga's separation of perception from language was in accord with them. Uddyotakara's commentary reaffirms Vātsyāyana's interpretation of this *sūtra* (1.1.4). Like Vātsyāyana, he states that the purpose of defining perception in this way is to stress that, since perception comes about as a result of contact between object and sense organ, no linguistic skills are necessary for its occurrence. This does not mean, however, that when we acquire those skills and begin to make judgments about our perceptions we are superimposing mental constructs, which have no basis in reality.

Hence for Uddyotakara physical objects are perceptual 'firsts' and he produces a dazzling array of counterarguments to defend Nyāya realism against Dignāga's offensive. As with Vātsyāyana, the recurring theme is that without the acceptance of a whole distinct from its component parts, we cannot explain how we arrive at the notion of an object such as a tree (see Sense perception, Indian views of §5). An additional argument which Uddyotakara uses concerns the relationship between vision and touch. For the Buddhist, there is no single entity apprehended by both vision and touch, so that we do not see the very same jar that we touch. Our conception of a jar arises from grouping a particular set of perceptual qualities together. Uddyotakara therefore argues from the premise that we do in fact have a cognition of a jar, and that only the Nyāya view of a substance as separate from

its qualities can explain this cognition that we all have. Udayana, in the *Ātmatattvaviveka (On the Discrimination of the Reality of the Self)*, was later to argue this same point in meticulous detail. Uddyotakara also addresses the difficult question of exactly how the whole is related to its parts. In answer to the question whether the whole resides in each of its parts partially or in its entirety, Uddyotakara replies that neither alternative is applicable. He resists all attempts to pull the whole apart and compares it to other entities, such as numbers, that are indivisible yet can be present in several things.

Uddyotakara employs a very similar argument when explaining the relationship between a universal (such as ‘cowness’) and the individual objects in which the universal is manifested (in this case, individual cows). As in the above argument, Uddyotakara deflects the question as to whether the universal is present in the individual in its entirety or in part. Universals are simple entities not subject to partition in this way, and they are related to the appropriate individuals by the relation of ‘inherence’. Despite Uddyotakara’s efforts, there is no doubt that the notion of real universals remains problematic for the Nyāya system. It might seem puzzling that the Naiyāyikas clung to it, especially given Uddyotakara’s recognition that in many instances we can explain our use of a common noun without invoking real universals. It would be a mistake, Uddyotakara tells us, to conjure up the notion of ‘cookness’ to explain how we label a variety of individuals as cooks. People are cooks in virtue of the fact that they all perform the common action of cooking, not in virtue of some universal inhering in them. Uddyotakara demonstrates a sophisticated understanding of language in his recognition that no uniform account can be given of how general terms function in a language. Many contemporary philosophers of language would agree. The role of real universals, such as ‘cowness’, was crucial, however, in the Nyāya account of causality (see Udayana) and in their attack on the Buddhist negative theory of meaning (*apohavāda*).

Ûisang (605-702)

Ûisang was the founder of the Korean branch of the Flower Garland (Hwaôm; in Chinese, Huayan) school of East Asian Buddhism which emerged as the main scholastic tradition within Korean Buddhism, thanks in large measure to Ûisang himself. His works emphasize the unimpeded interpenetration that Hwaôm posits to pertain between all phenomena in the universe.

Ûisang was ordained in the Silla kingdom of Korea, but soon decided to make a pilgrimage to the mecca of the Chinese mainland to study with Chinese teachers. After one unsuccessful attempt in 650, when he was repatriated to Silla on suspicion of espionage, Ûisang eventually arrived in Tang China in 661, where he became one of the principal disciples of the second patriarch of the Chinese Huayan school, Zhiyan (602-68). After his teacher's death he emerged as one of the two leaders of Zhiyan's congregation, along with Fazang (643-712). In 670, however, Ûisang learned of an imminent Chinese invasion of Korea and promptly returned to Korea to warn his king of the danger. The invasion forestalled, Ûisang was rewarded with munificent royal support and his Flower Garland School dominated Korean Buddhist scholasticism from that point onward.

Ûisang's works, though few in number, were extremely influential throughout East Asia and contributed much to establishing the doctrinal foundations for a distinctively Korean tradition of Buddhism. His vision of Buddhism is laid out in summary form in his principal work, the *Hwaôm ilsûng pôpkyedo (Diagram of the Flower Garland One-Vehicle Realm-of-Reality)*, a verse of 210 Chinese characters with accompanying autocommentary, written in 668 while he was still in China. The chart is a novel attempt to represent diagrammatically all the teachings of the *Avataṃsakasūtra (Flower Garland Scripture)*. Ûisang's poem is arranged in a wavelike form, the 'Ocean seal diagram' (*sagaramudrā-maṇḍala*), which represents the Flower Garland teaching of the 'six marks': universality and particularity, identity and difference, and integration and disintegration. The totality of the diagram represents the marks of universality, identity and integration, while its sinuous curves represent particularity, difference and disintegration. The one continuous line of the chart, upon which each individual logograph of the poem is superimposed, demonstrates the cardinal Flower Garland doctrine of the unimpeded interpenetration between all independent phenomena in the universe. The meanderings of the line of verse around the diagram's fifty-four corners symbolize the pilgrimage of the lad Sudhana to spiritual teachers, as recounted in the lengthy 'Entering the Realm of Reality' (*Gaṇḍavyūha*) chapter of the *Avataṃsakasūtra*. The fact that the snaking line of verse begins and ends at the same spot on the diagram illustrates the Hwaôm doctrine of soteriological interpenetration: the initial arousing of the thought of enlightenment (*bodhicittotpāda*), the inception of spiritual practice, is the same as complete, perfect enlightenment (*anuttarasamyaksaṃbodhi*), the consummation of that practice. Ûisang's autocommentary helps to elaborate the doctrinal implications of the diagram's visual form, creating a uniquely East Asian type of philosophical document.

Ulrich of Strasbourg (*c.*1220/5-1277)

A Dominican theologian and philosopher and a student of Albert The Great, Ulrich was well known for a widely studied summa theologiae, *De summo bono (On the Supreme Good), which represents an advance over previous summae in plan and organization. Ulrich provides a rich synthesis of Christian Neoplatonic theology and mysticism by systematizing the Aristotelianized Neoplatonic philosophical theologies of Albert the Great, Pseudo-Dionysius' De divinis nominibus and the Liber de causis. He exercised a notable influence on the Rhineland mystics.*

Ulrich was a student of Albert the Great at Cologne between 1248 and 1254; his fellow students included Thomas Aquinas and Hugh of Strasbourg. Ulrich was both a popular lecturer in theology at Strasbourg and, during the last five years of his life, the influential provincial of the German province. Ulrich was an intimate friend of Albert and his regular walking companion. Their long, warm friendship is evident in extant letters.

During the thirteenth century, Albert was the great figure in the Dominican school at Cologne from which his scientific interests and philosophical theology were transmitted through his immediate students Ulrich and Hugh to later important figures such as Dietrich of Freiberg and to the Rhineland mystics Meister Eckhart, John Tauler and Henry Suso. The dominant philosophical influences in the school were Aristotle, Proclus, Avicenna (see Ibn Sina), al-Farabi, Augustine, the *Liber de causis* (see Liber de causis) and Pseudo-Dionysius the Areopagite. Ulrich is deeply indebted to Albert's complex synthesis of the Augustinian theology of William of Auxerre and William of Auvergne, which was enriched with Aristotle's precise terminology, and the Neoplatonic ontology of Proclus and Pseudo-Dionysius.

Ulrich's works included commentaries on Aristotle's *Meteorology* and on Peter Lombard's *Sentences*. His only extant work is the summa *De summo bono (On the Supreme Good)*, composed between 1262 and 1272. Probably completed in eight books, the surviving manuscripts end at Book 6 tractate 5 and fill more than 600 folios; publication of the text is still in progress. The importance of the treatise is evident from the large number of manuscripts circulating in the thirteenth and fourteenth centuries. Ulrich was widely considered one of the most important Dominican thinkers after Albert and Thomas.

The treatise is organized according to an architectonic scheme derived from Peter Lombard. Book 1 concerns theology as science of the highest good; Book 2 concerns the being of the highest good; Book 3 concerns the Trinity; Book 4 concerns the Father and creation; Book 5 concerns Christ; Book 6 (200 folios) concerns the Holy Spirit and its ethical workings in human psychology; Book 7 concerns the sacraments; and Book 8 concerns beatitude and the attainment of the highest good (see Good, theories of the §1). The central themes of Ulrich's philosophical theology are presented in Books 1, 2 and 4.

The pervasive influence on Ulrich of the Christian Neoplatonist Pseudo-Dionysius is evident in the first two books, which comprise a loose commentary on the latter's *De divinis nominibus (On the Divine Names)*. In Book 1 tractate 1, the Neoplatonic metaphysics of light lays the foundation for an account of how the mind can know God. We know that God exists and what God is by means of the light conveyed by the angelic intelligences from the divine nature itself, both of which illuminate the agent intellect, the natural image of God in us. The theory of illumination endows the mind with the capacity to understand God in three ways: first, the negation of finite and imperfect properties generates infinite perfections which are worthy of the divine nature (symbolic theology); second, God is identified as the cause and source of all perfections (positive theology); and third, all properties are transcended in God (mystical theology) (see God, concepts of).

Book 1 tractate 2 argues that theology must be a supernatural science since even our natural knowledge of God's effects is not based on the dark and defective human intellect. It is faith, therefore, which presents God as the object of this science, and theology which grasps scientifically what is believed: God in himself and in his attributes, and God as both the supreme cause or first principle of creation and the supreme end or salvational goal of all. With greater precision and clarity than many scholastics, Ulrich articulates first principles for theological inquiry. In an Aristotelian manner, he argues that the four absolute first principles of theology, from which all other truths can be known, are immediately self-evident, again by means of intellectual illumination: (1) God is the

highest truth and the source of all truth; (2) this primary truth is infallible and warrants unconditional faith; (3) God's spokespersons must be believed; and (4) since it is inspired by God, Scripture must be true. It is only on the basis of the certain knowledge of these rules that the articles of faith, which are not evident in themselves, can be established. Book 2 expounds the divine names, divine substance and the transcendentals.

Book 4 tractate 1 examines the First Principle and its relations with created beings, and offers a compendium of Ulrich's doctrines in metaphysics, natural theology and cosmogony. His metaphysics of being derives from the *Liber de causis*: that 'being is the first among created things'. This Neoplatonic formulation holds that being is the first expression of or 'outflow' (*emanatio*) from God; it is the first form and basis of all other forms. Since being is universal it is indefinable in itself; but since being is mixed with non-being, it differs from the pure absolute being of God (see Being). Ulrich stresses that God must be distinguished from this universal being in order to avoid pantheism. The two realities also differ fundamentally as regards unity and relations. Universal being is not absolutely simple since it stands in real relations to non-being and God, for example, whereas God's pure unity is not abrogated by the relations of created beings to him. The rest of Book 4 comprises an extensive discussion of the Aristotelian causes and categories (tractate 2) and of transcendent substances and their mode of knowledge (tractate 3).

Ulrich's neglected treatise is a rich synthesis of the Christianized version of Neoplatonic themes scattered throughout the voluminous writings of Albert the Great. These include the identity of being and form, the hierarchy of intellects (Avicenna) combined with the doctrine of angels (Pseudo-Dionysius), the emanation of beings and forms from God via the process of universal illumination, and the confluence of being and value in the supreme principle.

Unamuno y Jugo, Miguel de (1864-1936)

The Spanish philosopher-poet Miguel de Unamuno upheld a heterodoxical Catholicism, resembling much nineteenth-century Liberal Protestantism, which viewed reason and faith as antagonistic. By 'reason', he understood scientific induction and deduction; by 'faith', a sentiment varying with his readings and personal experiences. Adolescent scepticism led him to reconcile science with religion by grafting Spencer's positivism onto various German idealisms, but a family tragedy brought this period of experimentation to an abrupt end. Obsessed with mortality, Unamuno achieved philosophical maturity with a blend of Liberal Protestant theology and the philosophies of James and Kierkegaard in his conception of the 'tragic sense of life' - the theme of his essays, novels, dramas, poetry and journalism. He acquired deep and intense insights into the quest for immortality. Unamuno was a professional in neither philosophy nor theology.

1 Life

Like many Spanish intellectual reformers of the late nineteenth and early twentieth centuries, Miguel de Unamuno sought to save Spain with rationalized religiousness. He dreamed of becoming the Spanish Luther. Brought up as a strict Catholic in the liberal Basque city of Bilbao, he lost his faith in Madrid of 1880, a city awash with many different philosophical currents, and thenceforth struggled to reconcile reason with religion and to stimulate Spaniards to follow his lead. To those ends he used his Chair in Greek Philology, obtained in 1891, and his controversial rectorship at the University of Salamanca (1901-14; 1930-6).

2 Reason and faith

Unamuno transposed problems of logic to the anthropological problem of life after death. Knowing that Hegel's dialectic somehow equated being and nonbeing, the sceptical young Unamuno of 1880 dreaded nonbeing after death. Hegel's logic starts from the datum of being (the thesis), whose indeterminacy is nonbeing (the antithesis). Thesis and antithesis rise to equality on a higher plane of discourse, the synthesis, termed by Hegel 'becoming'. By analogy, might not the negation of human being (death) imply salvation in a (higher) life eternal? Such a hope appeared in Unamuno's diaries and verses. In the 1880s he avidly read Herbert Spencer, who saw self-conscious individual existence as an incontrovertible truth, and in 1886 Unamuno began elaborating his own *'Filosofía lógica' ('Philosophy of Logic')* to unite Spencer with Hegel. Beginning with the undeniable fact of individual existence, Unamuno affirmed with Spencer the relativism of every relationship between subject and object (including mental representations of God and the soul). Unamuno called these representations 'images' in Hegel's sense of propositions or forms transcending common sense. Had the youthful Unamuno been bolder, he might have asserted endless individual existence as a matter of faith, defying common sense, yet demanded by a higher, rational dialectic; but he stopped himself making such a leap of faith.

Later he grafted Spencer onto a pre-existing system combining religion and science: Krausism, imported from Germany in 1844 (see Krause, K.C.F.). A leading Spanish Krausist, Unamuno's teacher Francisco Giner de los Ríos reinterpreted Krause to aid in the moral and intellectual reform of Spain. Younger Krausists sometimes adopted positivistic methods to buttress idealistic speculations, and styled themselves 'Krausopositivists'. Accordingly, Unamuno used Spencer to prove Krausist theories of human history in his influential 'Krausopositivistic' series of essays, En torno al casticismo (On Authentic Tradition) (1895). Here humanity is said to harmonize contraries such as reason and faith in a subrational collective heritage, the 'inner history'. However, Castilian intransigence hinders such syntheses and accounts for Spanish decadence. Unamuno's 1895 work helped writers of his literary generation of 1898 to explain Spain's defeat in her humiliatingly brief war with the United States.

Nevertheless, a personal crisis caused Unamuno to sweep aside previous intellectual accomplishments. In 1897, his son's death aroused in him nightmares of the abyss. Renouncing intellectualism, Unamuno sought to reconquer his childhood faith. He oscillated between retreating to orthodox Catholicism, converting to Liberal Protestantism, and yielding to scepticism. At the time, he was studying the prestigious Neo-Kantian school of Liberal Protestantism known as Ritschlianism, which he found compatible with Krausism. Aiming for an original philosophy of religion, he immersed himself in the history of Christian dogma as interpreted by the Ritschlian theologian Adolf von Harnack. Ritschl and Harnack held that Protestants, through justification by faith, receive

forgiveness for their sins and are consequently guaranteed salvation; while Catholics harbour doubts about salvation because of their indecisive theology. The troubled Unamuno uncritically accepted this Protestant opinion: hence the resemblances of his heterodoxy to conservative Ritschlianism. Yet in 1904 he valiantly tried to turn alleged Catholic uncertainty about salvation to his advantage, presenting it as a dynamic heritage he shared with all Spaniards. His concurrent readings in William James suggested the universality of the yearning for immortality.

Unamuno resolved to inculcate in his readers anxiety for their own immortality as a way to save Spain from dogmatic inertia. Spain's national Bible could be *Don Quixote*, whose hero equated the act of believing (*creer*) with creating (*crear*) its object: belief in a saving God makes the Saviour real. Just as Ritschl desired a nation of believers in forgiveness of sin, so Unamuno sought a nation of doubting believers in salvation. He modified Protestant thinkers such as Kierkegaard and Ritschl by substituting their concern about redemption with his own desire for immortality (see Ritschl 1883).

3 Chief works

Unamuno's main philosophical work, *Del sentimiento trágico dela vida en los hombres y en los pueblos (The Tragic Sense of Life)* (1911-12), contains a philosophy of religion more systematic than its doctrines allowed him to admit. Every flesh-and-blood human, Unamuno finds, desires immortality, but this desire clashes with sceptical scientific reason. If faith wins out, then God exists for human salvation; consists of Will and Personality, rather than of Reason; as Personality, is both finite and infinite, defying discursive reason; and is multifaceted and merciful enough to save every creature. Therefore the end of human history is the 'apocatastasis', the union of everything in God and the spiritualization of the universe. It is the human's moral duty to make the 'apocatastasis' a practical norm of everyday living and to deserve immortality. Structurally, Unamuno's system of ideas follows Ritschl's, which also begins with reflections on the conservation of personality, presents God as Personality and Love, and ends with an ethics of dominion over the world with devotion to vocation. Yet Unamuno substitutes considerations about life after death for Ritschl's concern with redemption here and now.

While *The Tragic Sense of Life* is Unamuno's most respected essayistic work, *La agonía del cristianismo (The Agony of Christianity)* (1931) is his most terse and anguished. Written in 1925 while Unamuno was in exile, this booklet derives the word 'agony' from the Greek word for struggle. Christianity entails struggle between universality and personalism; between truth, social and collective, and revelation, personal by essence; between Jewish belief in resurrection of the flesh and Hellenic credence in immortality of the soul; between monkish nihilism and the immortalizing desire for parenthood; between Catholicism and Protestantism, opposites which attract. Unamuno himself 'agonizes' while writing, hoping to serve Spain best by polemicizing from afar against her dictator Primo de Rivera.

The tragic sense of life generated Unamuno's best philosophical novels, *Niebla (Mist)* (1914), *Abel Sánchez* (1917) and *San Manuel Bueno, mártir (Saint Emmanuel the Good, Martyr)* (1933). *Mist* protests against the world-plan hypothesized by William James, with God and humans unfairly competing as if in a game of chess with an invincible champion. Unamuno yearned for a relationship of saving love between deity and humankind. His protagonist Augusto Pérez, confronting his Author-God Unamuno (a caricature of the flesh-and-blood author), anguishes for independence of his tyrannical creator. *Abel Sánchez* lodges a more specific protest against the world order, seen this time as a hospital for incurables afflicted by spiritual diseases, such as hate. Unamuno's modernization of the tale of Cain and Abel recounts Cain's experience from two tragically clashing viewpoints - the orthodox and the modern. Cain's malice is comprehensible both from the traditional standpoint, as envy, a sin, a disease, and, from the perspective of Unamuno's correspondent Croce, as the fact of human passion, capable of aggrandizing the individual.

In a subtler novelistic experiment, *Saint Emmanuel the Good, Martyr*, a beloved rural priest preaches immortality, in which he secretly does not believe. Greenfield (1979) defines him as a suicidal drive with a life-promoting direction. Ethically, his selflessness towards his parishioners daily helps spiritualize the universe; psychologically, his self-destructive tendency clashes with his desire for parenthood, which is equated in *The Agony of Christianity* to a yearning for immortality; existentially, he corresponds to Kierkegaard's individual feeling himself nothing before God, not because of sinfulness as in the case of the Danish philosopher himself, but because of doubt in immortality. In conclusion, though neither a professional philosopher like the Kierkegaardian phenomenologist

Heidegger, nor a professional theologian like the post-Ritschlian Barth, Unamuno expressed the tragedy of human mortality with multifaceted intensity.

Unconscious mental states

Unconscious phenomena are those mental phenomena which their possessor cannot introspect, not only at the moment at which the phenomenon occurs, but even when prompted ('Do you think/want/…?'). There are abundant allusions to many kinds of unconscious phenomena from classical times to Freud. Most notably, Plato in his Meno defended a doctrine of anamnesis *according to which a priori knowledge of, for example, geometry is 'recollected' from a previous life. But the notion of a rich, unconscious mental life really takes hold in nineteenth-century writers, such as Herder, Hegel, Helmholtz and Schopenhauer. It is partly out of this latter tradition that Freud's famous postulations of unconscious, 'repressed' desires and memories emerged.*

Partly in reaction to the excesses of introspection and partly because of the rise of computational models of mental processes, twentieth-century psychology has often been tempted by Lashley's view that 'no activity of mind is ever conscious' (1956). A wide range of recent experiments do suggest that people can be unaware of a multitude of sensory cognitive factors (for example, pupillary dilation, cognitive dissonance, subliminal cues to problem-solving) that demonstrably affect their behaviour. And Weiskrantz has documented cases of 'blindsight' in which patients with damage to their visual cortex can be shown to be sensitive to visual material they sincerely claim they cannot see.

The most controversial cases of unconscious phenomena are those which the agent could not possibly introspect, even in principle. Chomsky ascribes unconscious knowledge of quite abstract principles of grammar to adults and even newborn children that only a linguist could infer.

Many philosophers have found these claims about the unconscious unconvincing, even incoherent. However, they need to show how the evidence cited above could be otherwise explained, and why appeals to the unconscious have seemed so perfectly intelligible throughout history.

1 What counts?

Some care is needed to define exactly what counts as unconscious. Not just any phenomenon that fails to be conscious is *unconscious* in the intended sense. Thus, planets do not unconsciously follow elliptical orbits; nor does one's stomach unconsciously follow rules for digesting food; nor (to take a fallacy from popular biology) do we or our genes unconsciously seek replication when we act in ways that may in the past have had that consequence. We might call these phenomena simply '*non*-conscious', distinguishing as *un*conscious only those *mental* phenomena of which the possessor could not be made aware at the time of their occurrence, even if prompted. Thus, planets, stomachs and genes are non-conscious, having no mental lives at all.

But this definition is not quite enough. Suppose it were true that someone, Seymour, unconsciously feared castration; and suppose that Seymour read in a book that all men unconsciously fear castration, and concluded *merely* from this that he, too, must have such a fear. Presumably his unconscious fear would not *thereby* have been rendered conscious. The fear remains 'unconscious' so long as he is not conscious of it in the *right*, 'introspective' sort of way. Specifying this right way may be none too easy; but this is a problem that arises with respect to other mental phenomena (for example, the relation of intentions to the intended act).

Whyte (1978) has usefully compiled allusions to unconscious processes from classical times to Freud (not always distinguishing, however, between unconscious and non-conscious). Not only did Plato posit unconscious memories (see Plato §11), but the Greek physiologist, Galen, postulated unconscious inferences in perception and Plotinus, 'feelings without awareness'. Aquinas inferred the existence of unconscious 'processes of the soul' from the fact that he 'did not observe [his] soul apart from its acts'. Leibniz argued that ordinary perceptions must be the result of innumerable smaller perceptions occurring below a quantitative threshold (see Leibniz, G.W. §8). Unconscious thoughts and desires were a common theme among eighteenth- and nineteenth-century romantic poets and philosophers, such as Herder, Novalis, Richter, Wordsworth, Hegel and Schopenhauer; and, anticipating contemporary computational models of mind, the great nineteenth-century psychologist, Helmholtz, developed a fairly elaborate theory of unconscious inferential processing (see Helmholtz, H. von §2) Much of this served as the background for perhaps the most famous advocate of the unconscious, Freud.

2 Freud

Sigmund Freud postulated unconscious mental states to explain a wide variety of behaviours. His earliest evidence came from experiments involving hypnotic suggestion, experiments which, though fascinating, remain still quite controversial (see Hilgard 1977). Freud's primary argument is that parapraxes (for example, slips of the tongue), dreams, hysterical and neurotic symptoms, even 'ideas that come into our head we do not know from where' remain 'disconnected and unintelligible' if we insist that all mental states are conscious, whereas they 'fall into a demonstrable connection if we interpolate between them the unconscious acts we [psychoanalysts] have inferred' (1915: 168). Moreover, he argues, if it turns out that this interpolation enables us to 'exert an effective influence upon the course of conscious processes, this success will have given us an incontrovertible proof of the existence of what we have assumed' (1915: 168).

'Incontrovertible' seems a little strong. Certainly there *could be* plausible theories of 'the ideas that come into our head', and perhaps even of dreams and neuroses, that do not postulate unconscious mental states: especially the random flow of ideas in both dreams and daily life could have a purely physical explanation. Of course, we can imagine a standard mentalistic explanation in terms of beliefs and motives. But it is not enough to imagine the pattern; one has to provide some reason to think the pattern is genuine. For example, one has to find some critical evidence that could not be explained by any independently warranted purely physiological hypothesis. Of course, these latter explanations may not make a person's behaviour 'intelligible', if what that means is that they should be seen as part of some kind of 'rational' or 'symbolic' pattern. There is no doubt that Freud's explanations often possess an extraordinary charm in this way (Wittgenstein 1966). But then we need an argument that the charming pattern Freud seeks actually corresponds to any real processes in a person's mind. Perhaps there is no true *causal* explanation of dreams or neuroses that makes them 'intelligible' in *that* particular way.

Freud's further argument from therapeutic success is, moreover, a notorious fallacy: the history of religion and psychotherapy is full of success stories involving theories that there is no serious reason to believe. Many such effects may well be due to suggestion or well-established 'placebo' effects, whereby someone's belief merely that they have been cared for at all can actually improve their condition (Grünbaum 1984). None of this implies that Freud's postulations are *false*. The point is that the truth in this domain may be harder to ascertain than Freud recognizes.

What Freud needs, and sometimes does provide, are regularities that could not be explained except by adverting to the specific contentful states he posits. He and Breuer began to do this when they noted that hysterical patients were often 'paralysed' not at places at which normal paralyses occurred, but, rather, at places that were *popularly and mistakenly believed* to be subject to paralysis (for example, 'glove' anaesthesia). Here the only plausible explanation of such curious paralyses involves appeal to the *content* of those popular beliefs, and this it does whether or not the believer is aware of that content.

Freud's actual account of the unconscious (in what he sometimes calls 'the truly dynamic sense', and which he comes to call the 'id') is actually quite special. He thinks that unconscious or 'primary' processes are intellectually quite primitive: they have no representation of negation, degrees of certainty, time or an independent reality, and are only subject to 'the pleasure principle'. Interestingly, he denies the existence of unconscious *affect* (Freud 1933). Nevertheless, he claims, 'every psychical act begins as an unconscious one, and…may remain so or go on developing into consciousness according as it meets resistance or not' (1915: 55). It appears that the only reason he can see for material not becoming conscious is that it has been in this way censored or 'repressed'. It seems not to have occurred to him that there could be other reasons for material to remain unconscious: for example, that there may not be the right kind of causal or 'informational' path between the material and mechanisms of introspection (see Psychoanalysis, methodological issues in).

3 Recent experiments

This latter possibility emerges in contemporary cognitive science. In an influential article, Nisbett and Wilson (1977) reviewed a wide range of experiments in which people can be shown to be sensitive to a variety of what would appear to be conceptualized contents, but without any awareness of them. Instead of noticing these factors, the subjects frequently 'introspect' material that can be independently shown to be irrelevant to the causation of their behaviour. Indeed, even when explicitly asked about the relevant material, they will deny that it played any

role. For example, Latané and Darley (1970) showed that subjects are less likely to aid strangers in distress the greater the number of bystanders in the situation, but with no awareness of this effect. And Nisbett and Wilson (1977) asked fifty-two subjects to choose between what were (unknown to them) four *identical* pairs of nylon stockings presented in a left-to-right array: 80 per cent of them tended to choose the right-most pair; but, when asked, virtually all subjects denied that position had any effect. Similar results obtain for cognitive dissonance, subliminal clues in problem solving and semantic disambiguation, and subtle perceptual cues, such as the dilation of pupils in a face (Hess 1975).

One of the most philosophically interesting phenomena supporting the evidence for unconscious mental states is that of 'blindsight'. This occurs in patients who have suffered damage to their visual cortex and who claim not to be able to see various stimulus materials that have been presented to them; nevertheless, they can be shown to score well above chance when they are forced to 'guess' at what they may be seeing (Weiskrantz 1986).

What exactly such data show about the *extent* of unconscious processes is still a matter of considerable controversy. Velmans (1991), supporting Lashley (1956), argues that all cognitive processes can occur unconsciously. In an important study, Ericsson and Simon (1984) try to sort out the different informational paths involved in different mental processes such as perception, long- and short-term memory retrieval, and in a person's surmises about the causation of their behaviour, arguing that some of these paths do and some do not provide a basis for genuine introspection.

4 Chomsky

All the examples considered so far are examples of cognitive contents that people would at least ordinarily *understand*. However, more theoretical cognitive scientists, influenced especially by the linguist, Noam Chomsky, often ascribe quite technical contents even to newborn children. Chomsky (1986) argues, for example, that the best explanation of the rapidity with which children acquire natural language is that they have innate knowledge of general principles of what he calls 'universal grammar' (see Language, innateness of). This includes such principles, for example, as that a pronoun cannot be used to refer to something picked out by a noun in a clause subordinate to the clause in which it occurs. For example, in sentence (1), 'he' cannot be knowingly used to refer to John, although it can in (2):

(1) He hoped John would win.
(2) John hoped he would win.

The full statement of the rules for pronouns is actually quite technical, involving notions such as 'c-command' and 'phrasal head' that require a good deal of theoretical study to understand. If a newborn child is said to 'know' such a principle, it would patently be a piece of unconscious (or 'tacit') knowledge, at least in the sense that the child is entirely unable to express it, even when prompted. Indeed, there is no *introspective* route even in an adult linguist from the unconsciously known principle to any awareness of it.

Chomsky's research has stimulated an entire movement not only in linguistics, but in many other parts of psychology (for example, vision, reasoning, cognitive development), where knowledge of similarly abstract principles about material objects, biological kinds and folk physics are also attributed to adults and young children alike. In a different vein, Polanyi (1967) has stressed the role of 'tacit' knowledge in guiding creativity and scientific research (see Knowledge, tacit; Nativism).

There can be no doubt that much of the evidence adduced by Chomsky and these other psychologists is impressive and cries out for explanation, which is not easy to provide. But many philosophers doubt that the explanation needs actually to claim that people *know*, *believe* or, in Chomsky's phrase, even 'cognize' (1986: 265) the relevant principles. It may be enough that they simply *obey* the principles in the way that their bodies obey the laws of gravity, without *following* them, indeed, without them being represented or otherwise part of their *mental* lives. They may explain people's knowing *how* to do certain things, without requiring that they know *that* certain principles obtain (see Ryle 1949; Devitt and Sterelny 1989).

Much here depends upon being clearer than anyone is about what is required for ascribing any mental content at all. Quite apart from issues of awareness, Davidson (1980) claims that content ascription only makes sense when many contents are ascribed as some kind of interacting rational system. If so, then many of Freud's and

Chomsky's claims would appear to be in trouble: as Stich (1978) points out, if Chomsky were correct, someone could know innately some principle *P*, be convinced as an adult that *P* entailed *Q*, but not be the least disposed to infer *Q*. But then, on a Davidsonian view, that should be a reason not to ascribe *P* to that person in the first place.

Stich proposes thinking of Chomsky's grammatical principles as contents occurring at a different, 'sub-doxastic' level of psychology, a suggestion taken up systematically by Fodor (1983) in his postulation of 'informationally encapsulated modules' of the mind (see Modularity of mind). But the question persists: why think that the principles comprise genuine *mental contents* inside a module? Peacocke (1989) suggests that it is enough that a system be 'sensitive to the information' expressed by the principle. But this seems too broad: for example, if we are to take talk of 'genetic information' seriously, DNA would seem to have contentful attitudes about the structure of amino acids.

5 Philosophical qualms

A number of philosophers have objected to the postulation of unconscious mental states. McIntyre (1958) and Searle (1992) have insisted that it is some sort of conceptual truth that mental states involve at least a disposition to have certain experiences. Searle, for example, defends what he calls the 'connection principle', according to which 'we understand the notion of an unconscious mental state only as…the *sort of thing* that…could be…conscious' (1992: 155-6). Now, of course, *any* contents - from the most abstruse Chomskean principles to the most sordid of Freudian analyses - are, for almost anyone, 'possible contents of consciousness': most people can be brought at least to *understand the words*. Reiterating the point we made early on, what Searle presumably means is that mental contents have to be *accessible* to their possessor in something like the normal introspective way, whatever way that is. But once one reflects on how very special that way may be, it is puzzling why the existence of a mental state should depend upon it.

Strawson goes further and claims that 'there are, strictly speaking, no dispositional non-experiential mental phenomena' (1994: 167), comparing a non-experiential brain to a CD recording of a Beethoven quartet that is not currently being played, and which could be used either to produce a genuine acoustical event on a CD player or a light show.

What tells against all this scepticism, however, is the explanatory usefulness of unconscious intentional states having genuine causal powers. Freud's and contemporary cognitive postulations of unconscious states are interesting because, if true, they would explain certain *content-sensitive* behaviours, such as parapraxes, neuroses, and differential willingness to come to the aid of strangers; Chomsky's, because, if true, they would explain language acquisition. Weiskrantz's postulation of'blindsight' explains his patients' ability to perform better than chance at picking out stimuli of which they are unaware. The crucial difference between Strawson's example of the unplayed CD and the unconscious brain is that, whereas the *musical* properties of the unplayed CD are, indeed, at that time causally inert, the intentional content properties of these unconscious mental states are not. If Freud, Chomsky, Nisbett and Wilson or Weiskrantz are correct, they are responsible for a variety of observable phenomena. Someone sceptical of unconscious states needs to show how all the phenomena these figures cite can be otherwise explained.

Searle does provide a further argument against entirely unconscious states, claiming that no postulation of an attitude lacking consciousness can account for 'aspectual shape' (1992: 156-61, 169-72), or what is better known as the phenomena of (hyper-)intensionality, whereby minds are able to distinguish among even necessarily coextensive concepts, such as [water] and [H_2O]. Searle believes that only a conscious mind can possess such an ability (see Bealer 1984 for a similar, more formidable argument).

A full reply to this point would require setting out the various proposals of a great number of writers regarding how the problems of both intentionality and (hyper-)intensionality are to be solved. Suffice it to say that there are a number of possibilities to be considered in detail. For example, many think that a computational theory of mind involving a language of thought, endowed with both narrow and wide contents, will suffice (see Language of thought; Content: wide and narrow). Many different sentences with different causal roles within the mind - for example, 'Water is wet', 'H_2O is wet' - may express the same *wide* content, and so constitute different 'aspectual shapes' of that content. Searle would in turn reject such an account, invoking his 'Chinese room argument'; however, the soundness of this argument is widely disputed (see Chinese room argument).

In any case, the fact that so many people, from antiquity to the present, find the postulation of unconscious phenomena both intelligible and illuminating provides an at least *prima facie* case that they are not incoherent in the ways these philosophers claim. Indeed, until better explanations of the various phenomena we have discussed are presented, that postulation needs to be taken seriously.

Underdetermination

The term underdetermination refers to a broad family of arguments about the relations between theory and evidence. All share the conclusion that evidence is more or less impotent to guide choice between rival theories or hypotheses. In one or other of its guises, underdetermination has probably been the most potent and most pervasive idea driving twentieth-century forms of scepticism and epistemological relativism. It figures prominently in the writing of diverse influential philosophers. It is a complex family of doctrines, each with a different argumentative structure. Most, however, suppose that only the logical consequences of a hypothesis are relevant to its empirical support. This supposition can be challenged.

1 Relevant terminology

The thesis of underdetermination involves a set of specific claims about the relations between bodies of evidence or statements about that evidence, on the one hand, and theories, on the other. All forms of that thesis insist that multiple, mutually incompatible, theories can enjoy the same relation to any given body of evidence. Beyond that point of agreement, however, there are more and less ambitious versions of underdetermination. A few terminological preliminaries are in order before we proceed to examine some of them. To facilitate comparison of the various versions of underdetermination, I shall use this vocabulary: *e* will refer to whatever evidence is in hand; *c* will refer to relevant rules or criteria for choosing between hypotheses; and I shall further suppose that we are confronted by a single hypothesis *h* or, more commonly, by a set of rival hypotheses, $h_1, h_2, \ldots,_n$ (some of which may not have been explicitly formulated).

Now, what every version of the thesis of underdetermination shares in common is this claim: that the relevant criteria, *c*, and available evidence, *e*, will provide no rational grounds for preferring h_i to some (and perhaps not to any) of the rivals to h_i. Various versions of the thesis of underdetermination explore its plausibility under various interpretations of *c*, the criteria of appraisal.

2 Deductive and ampliative underdetermination

Hume argued convincingly that one cannot derive a genuinely universal statement from any finite set of its positive instances (see Hume, D. §2). This is surely correct, but what does it entail for the theory of knowledge? One thing it certainly shows is that if the only criteria of theory choice we allow are those of deductive logic, then the rational acceptance of a theory is always underdetermined by any conceivable evidence. Karl Popper explicitly drew this moral fromHume’s work (see Popper, K.R. §2). It explains why Popper resisted the idea that positive belief in a theory could ever be rational. (Belief for Popper, as for Hume, was a matter of ‘animal instinct’.)

Most philosophers refuse to follow Popper in supposing that the rules of deductive logic exhaust the epistemic and methodological resources available for the appraisal of hypotheses. They believe that there are various principles of ampliative inference that come into play in the evaluation of hypotheses. The fact that deductive logic underdetermines theory choice leaves open, they insist, the possibility that these other nondeductive principles may guide theory choice unambiguously.

One plausible, if simplistic, ampliative rule of theory evaluation is what Carl Hempel called the Nicod criterion (1965). According to this idea, if some *h* entails a particular observation report, then the truth of that observation report counts as evidence for *h*; if the observation report is false, then it counts as evidence against *h*. About a century ago, Henri Poincaré and others stressed the significance of the fact that, through any finite number of points, indefinitely many curves could be drawn. This made clear that indefinitely many alternative hypotheses were compatible with (indeed, deductively entailed by) any given body of data. If one supposes, with the Nicod criterion, that the potential evidence for *h* consists simply in its observational consequences, then it is clear that indefinitely many different and conflicting hypotheses will share the *same* evidential instances. If we take the Nicod rule as a criterion for hypothesis evaluation, it follows that, whenever we are confronted with an *h* enjoying apparent evidential support (that is, having many true positive or entailed instances), we know that there will be indefinitely many incompatible hypotheses possessing those same instances as ‘evidence’ - even if we cannot formulate them. In sum, theory choice is underdetermined by any methodology which countenances all and only the known positive (or otherwise entailed) instances of a hypothesis as confirmatory.

Nelson Goodman’s new riddles of induction provided concrete illustrations of the point (1965). Consider a hypothesis like ‘all emeralds are green’ and a contrived rival like ‘all emeralds are green before the year 2000 AD and blue thereafter’. If our observations consist entirely of green-appearing emeralds examined before 2000, then both hypotheses can claim all the same positive instances. Prior to the year 2000, the evidence, however extensive, appears impotent to guide choice between them (see Goodman, N. §3; Induction, epistemic issues in).

It is important to note that, even if hypothesis choice is underdetermined in this specific sense, that does not entail that *every* rival to a given *h* will fare as well as *h* does. It means, rather, that *there will be* rivals which will fare as well.

3 Holistic underdetermination (the ‘D-thesis’)

Arguments of a very different sort undergird an even more global form of underdetermination. During the 1950s, W.V. Quine revived arguments made earlier in the century by Pierre Duhem (1906) about the inconclusiveness of falsification (see Duhem, P.M.M.; Quine, W.V. §3). Specifically, the Duhem thesis (D-thesis) holds that hypotheses never approach the tribunal of experience singly but only as parts of much larger webs of belief. This must be so, since auxiliary hypotheses are typically needed even to determine what a given hypothesis predicts about experience. Suppose, asks Quine, that the result predicted by a web of such hypotheses turns out to be mistaken? In that case, he maintains, all we have learned is that we have made a mistake somewhere in our body of beliefs but that blame cannot be further localized. Moreover, he insists that we can hang on to any particular hypothesis we like ‘come what may’, since we can always blame any empirical failures of the web on other strands. More precisely, Quine holds that *any* given *h* can be maintained in the face of any apparently negative evidence because (he thinks) there will always be some auxiliary that can be legitimately invoked which will bring *h* into line with whatever we observe. Any *h* can, with suitable changes elsewhere in our beliefs, be made to explain any evidence. Although Quine and others have repeatedly asserted this thesis to be true, it has never been proven that every apparently refuted hypothesis can be saved in the face of any evidence by invoking a nontrivial auxiliary hypothesis.

If, however, this is correct, then we have a much more global sort of underdetermination to contend with. Whereas previous versions of the underdetermination thesis argued that, for any apparently successful *h*, there will be at least one rival which exhibits the same success, the holistic version of the underdeterminationist thesis seems to say that, given any apparently successful *h*, *all* of its rivals can be made to fit the same evidence that supports *h*, whatever *e* is. This view appears to entail a thesis of cognitive egalitarianism, namely, that all rival hypotheses can - with sufficient ingenuity - be made to appear equally well supported by whatever evidence is in hand.

4 Undermining underdetermination

What Quine’s version of the underdetermination thesis takes for granted, as do virtually all others, is the idea that a hypothesis’ entailed instances are coextensive with its epistemically supporting instances. He is committed to this since he countenances two hypotheses as equally well supported by *e* provided that both hypotheses entail *e*. This idea, the Nicod criterion, undergirds the paradoxes of confirmation, the Goodman paradoxes of induction and Quinean underdetermination.

Those who are less taken with the underdetermination thesis believe that its identification of entailed consequences with evidentially supporting instances rests on a misunderstanding of how empirical support works. Specifically, it is easy to show both (a) that many entailed instances of an hypothesis lend it no empirical support and (b) that much of the support enjoyed by many hypotheses comes from outside the set of its entailed consequences. As an example of (a), consider the fact that data used to fix the parameters of a hypothesis, by virtue of being built into *h* itself, cannot then be used as reasons for accepting *h*, even though (trivially) *h* entails them. As regards (b), it is virtually a truism that hypotheses can derive evidential support from instances not entailed by those hypotheses. For instance, the information that the last 10,000 crows have been black is evidence for the hypothesis that the next crow I observe will be black, even though that latter hypothesis entails nothing about the 10,000 crows. Equally, probabilistic statements (for example, ‘most humans die before the age of 100’) typically do not entail any specific claim about observed relative frequencies, even though those same relative frequencies can both confirm and disconfirm statistical hypotheses. Even with respect to a nonprobabilistic hypothesis, one can often derive empirical support from evidence which *h* does not entail but which is entailed by yet more general

hypotheses that in turn entail *h*. Thus, after the Newtonian synthesis, evidence about bodies falling on the face of the earth supports Kepler's laws, even though Kepler's laws themselves entail nothing whatever about cases of terrestrial free fall.

In sum, the supporting instances for a hypothesis are not coextensive with its entailed instances nor are its undermining instances exclusively those denied by *h*. Where does this leave the thesis of underdetermination? Because all the advocates of underdetermination have operated with this mistaken notion of empirical support - which assimilates support to being a logical consequence of a hypothesis - we do not presently know whether choice of theory is underdetermined by the evidence. While we do know that rival theories may well have the same known empirical consequences, this knowledge seems to be irrelevant to questions of empirical support, since there are ample grounds for denying that empirical consequences and supporting instances amount to the same thing.

It should be noted, finally, that virtually all formulations of the thesis of underdetermination presuppose that, in judging whether the available evidence supports a given hypothesis, we must assure ourselves that there is no *possible* hypothesis which could be equally well supported. The idea that extant hypotheses are being compared (at least implicitly) with all possible rival hypotheses is probably a hyperbolic view of the theory choice situation. Scientists repeatedly point out that the problem generally facing them is finding even one hypothesis that will fit with the available evidence. The philosopher's penchant for supposing that the function of evidence is to enable one to choose, not merely between extant hypotheses, but between all possible hypotheses is a conceit that could profitably be dispensed with.

Unity of science

How should our scientific knowledge be organized? Is scientific knowledge unified and, if so, does it mirror a unity of the world as a whole? Or is it merely a matter of simplicity and economy of thought? Either way, what sort of unity is it? If the world can be decomposed into elementary constituents, must our knowledge be in some way reducible to, or even replaced by, the concepts and theories describing such constituents? Can economics be reduced to microphysics, as Einstein claimed? Can sociology be derived from molecular genetics? Might the sciences be unified in the sense of all following the same method, whether or not they are all ultimately reducible to physics? Considerations of the unity problem begin at least with Greek cosmology and the question of the one and the many. In the late twentieth century the increasing tendency is to argue for the disunity of science and to deny reducibility to physics.

What kinds of integration are manifested, or sought after, in the claims and practices of the different fields of inquiry we call ‘sciences’? This question should be carefully distinguished from any of the different specific theses addressing it and yet it should be stressed as the linking thread of a time-honoured philosophical debate. The question belongs to a tradition of thought that can be traced back to Presocratic Greek cosmology, in particular to the preoccupation with the question of the one and the many. In what senses are the world, and thereby our knowledge of it, one? A number of representations of the world emerged in terms of its decomposition into a few simple constituents: Parmenides’ static substance, Heraclitus’ flux of becoming, Empedocles’ four elements, Democritus’ atoms, or Pythagoras’ numbers, Plato’s forms, Aristotle’s categories.

With the advent and expansion of Christian monotheism, the organization of knowledge reflected the idea of a world governed by the laws dictated by God, creator and legislator. Encyclopaedic efforts such as the Etymologies, compiled in the sixth century by Isidore, Bishop of Seville, the works of Ramon Llull in the Middle Ages and of Petrus Ramus in the Renaissance emerged from this tradition. Llull introduced tree-diagrams and forest-encyclopedias organizing different disciplines (including law, medicine, theology and logic). He also introduced more abstract diagrams - not unlike some found in Kabbalistic and esoteric traditions - in an attempt to encode combinatorially the knowledge of God’s creation in a universal language of symbols. Ramus introduced diagrams representing dichotomies and gave prominence to the view that the starting point of all philosophy is the classification of the arts and sciences.

The emergence of a distinctive tradition of scientific thought addressed the question of unity through science’s designation of a privileged method, set of concepts and language. Francis Bacon held that a unity of the sciences emerges out of our classifications of material facts in the form of a pyramid with different levels of generalities. Galileo Galilei proclaimed that the Book of Nature was written by God in the language of mathematical symbols and geometrical truths: the story of Nature’s laws is told in that language in terms of a reduced set of primary qualities - extension, quantity of matter and motion.

Descartes and Leibniz gave this tradition a rationalist twist centred on the powers of human reason. Like Llull’s, their conception of unity is combinatorial, that is, determined by rules of analysis and combination. According to Descartes the science of geometry, with its demonstrative reasoning from the simplest and clearest thoughts, constitutes the paradigm for the ideal of unification of all knowledge (see Descartes, R. §§2-3). Descartes symbolized this unity again using the image of a tree. Unlike in the manual arts, there should be no division of labour in the sciences; they ought not to be studied separately according to their subject matter. Leibniz proposed a ‘general science’ in the form of a Demonstrative Encyclopaedia. This would be based on a ‘catalogue of simple thoughts’ and an algebraic language of symbols, ‘characteristica universalis’, which would render all knowledge demonstrative and allow disputes to be resolved by precise calculation (see Leibniz, G.W. §10).

The notion of unity of science, along with that of the universality of rationality, was given its strongest promotion during the European Enlightenment. The most important expression of the encyclopaedic tradition came in the mid-eighteenth century from Diderot and D’Alembert, editors of the *Encyclopédie* (1751-72). Diderot stressed in his own entry, ‘Encyclopaedia’, that ‘the word Encyclopaedia signifies the unification of the sciences’. The function of the encyclopedia was to exhibit the unity of human knowledge. Diderot and D’Alembert, in contrast with Leibniz, made classification by subject primary, and introduced cross-references by way of logical

connections.

For Kant the unity of science is not the reflection of a unity found in nature; rather, it has its foundations in the allegedly unifying nature of reason itself (see Kant, I. §7). This, however, lacks the Leibnizian form of a deductive system and combinatorial framework. Instead, Kant adopts the image of an organic architecture. Each science is a self-subsistent whole and separate buildings connect to other sciences by passages. He also held the view that biology cannot be reduced to mechanics.

Kant's ideas set the frame of reference for discussions of unification in German thought throughout the nineteenth century. He gave philosophical currency to the notion of world-picture (*Weltbild*), establishing unity of science as an intellectual ideal. Influenced by this tradition, which culminated with the work of Albert Einstein, the physicists Max Planck and Ernst Mach engaged in a heated debate about the precise character of the unified scientific world-picture. Mach's, more influential, view was phenomenological and Darwinian: the unification of knowledge took the form of an analysis of ideas into elementary sensations and was ultimately a matter of adaptive economy of thought. In physics the 'electromagnetic world-picture' and Planck's thermodynamical worldview constituted some of the alternatives to a long-standing mechanistic view that since Newton had affected biology as well as most branches of physics.

Kant also distinguished between several types of judgement that, in turn, characterized different intellectual disciplines. In this way he set the basis for the famous distinction between the natural sciences (*Naturwissenschaften*) and the cultural or social sciences (*Geisteswissenschaften*) introduced by Wilhelm Dilthey. Followers of this distinction, such as Max Weber and Heinrich Rickert (for Rickert, see Neo-Kantianism §7), claimed that the difference in subject matter between the two kinds of science forced a distinctive difference between their respective methods - this despite the fact that since Hume, Comte and J.S. Mill, the social sciences had relied on analogies with the natural sciences, from Newtonian and statistical mechanics and also from biology.

The logical positivists, notably the members of the Vienna Circle, introduced, under the banner of 'unity of science without metaphysics', a model of demarcation between science and metaphysics based on the unity of method and language that included all the sciences, natural and social (see Demarcation problem; Logical positivism; Vienna Circle). Notice that a common method does not imply a more substantive unity of content involving theories and their concepts. In the stronger model especially recommended by Rudolf Carnap, however, unity was affirmed because of the associated value of simplicity, and was characterized by axiomatic structures, reductive logical connections between concepts, and laws of the different sciences at different levels, with physics as the fundamental basis, and the possibility of empirical grounding and testability. Carnap was influenced by the empiricist tradition (especially Russell and Mach) and the ideals of simplicity and reductive logical analysis in the early works of Russell and Wittgenstein (see Analytical philosophy §2). Otto Neurath, by contrast, favoured a more realistic and less reductive model of unity which emphasized a unity of language and the local exchanges of scientific tools, although it was not constrained by Carnap's ideals of conceptual precision, deductive systematicity and logical rigour (Neurath spoke of a 'boat', a 'mosaic', an 'orchestration', a 'universal jargon'). In 1934 Neurath spearheaded a movement for Unity of Science that encouraged international cooperation among scientists and launched the project of an *International Encyclopedia of Unified Science*. For both Carnap and Neurath the ideal of unified science against metaphysics had deep social and political significance.

Two new ideas by logical positivists in the USA after the Second World War again placed the question of unity of science at the core of philosophy of science: Carl Hempel's deductive-nomological model of explanation and Ernest Nagel's (1961) model of reduction (see Explanation; Reduction, problems of §§2-3). Hempel's model characterizes the scientific explanation of events as a subsumption under an empirically testable generalization. In the 1950s, when positivism was extending to the social sciences, the model was offered as a criterion of demarcation. Explanations in the historical sciences too must fit the model if they are to count as scientific (see Positivism in the social sciences §2). The applicability of Hempel's model was soon contested - notably by W. Dray - and this opened a debate about the nature of the historical sciences that remains unresolved. In the process, some have claimed as historical natural sciences the like of geology and biology. It has been argued that Hempel's model, especially the requirement of empirically testable strict universal laws, is satisfied neither in the physical sciences nor the historical sciences, including biology (Cartwright 1983; Ehreshefsky 1992).

Since Nagel's influential model of reduction by derivation, most discussions of unity of science have been cast in

terms of reductions between concepts and between theories. The hierarchy of levels of reduction was set by the levels of aggregation of entities all the way down to atomic particles, thus rendering microphysics the fundamental science (Oppenheim and Putnam 1958). Criticism for the rejection of Nagel's model and its emendations has occupied the last three decades of philosophical discussions of the unity of physics, and especially in psychology and biology. In the latter the availability of laws and theories and the feasibility of global reductions have been contested (see Reductionism in the philosophy of mind). The possibility and the necessity of reductions in a number of forms have been discussed in connection with issues of explanation, realism and scientific progress (see Naturalized philosophy of science §1). Debates on unification and reduction have taken place also within the sciences as renewed reductionistic ideals have been revived in physics, driven by the success of the unified theories of fundamental forces in the 1970s, and in biology - especially sociobiology - driven by successes in molecular genetics (see Molecular biology; Sociobiology).

In anti-reductionist quarters, models of unification without reduction have appeared: for instance, the notion of 'interfield theories' (Darden and Maull 1977) and, less theory-oriented, the emphasis on the plurality of kinds of unity (Hacking 1996) and the idea of science as a historical process, manifesting a historical unity with a Darwinian-like pattern of evolution (Hull 1988). A more radical departure is the more recent criticism of the methodological values of reductionism and unification in science - also as embedded in society and affecting it. This view argues for the replacement of the emphasis on global unity - including unity of method - by the emphasis on disunity, epistemological and ontological pluralism and local cooperation. The suggestion is that the notion of a science should be understood, now following the later Wittgenstein, as at best a family resemblance concept (Dupré 1993).

Universal language

Most often associated with attempts to establish an international language such as Esperanto, the idea of a universal language is rooted in the biblical claim of an original language common to all human beings. The idea received its most thorough investigation during the seventeenth century. Drawing on the example of Chinese characters, early schemes involved a system of written signs that would allow communication between speakers of different languages. Later thinkers argued for the importance of an ideal 'philosophical language' in which the structure of signs exactly mirrored the structure of reality. While such projects fell short of their authors' expectations, their influence can be discerned in the formalisms of modern logic and science.

1 Adamic language

The earliest source for the idea of a universal language is the biblical story of an original language used by Adam to name the different species of animals created by God (*Genesis* 2: 19-20). In both the Jewish and Christian traditions, it was commonly assumed that this 'Adamic' language expressed Adam's perfect knowledge of things prior to the Fall: each name of a creature exactly conveyed its essence. It was natural to suppose a corruption of this language at the Fall; however, the crucial event in the loss of a universal language is told in the story of Babel, when 'the Lord confused the language of all the earth' (*Genesis* 11: 9). Thereafter, human beings were condemned to speak a multitude of languages and to suffer the pain of mutual incomprehension.

This biblical background remained central to conceptions of a universal language well into the seventeenth century. Numerous attempts were made to identify and recover the original language of Adam. Among Jewish and Christian thinkers alike, Hebrew retained the greatest claim to this honour, although other candidates were proposed (including Latin, Chinese, Dutch and Swedish). The attempt to recover the Adamic language, and the knowledge implicit in it, was significantly influenced by the Jewish kabbalah, which assigned a mystical significance to the letters of the Hebrew alphabet and prescribed techniques for their interpretation and manipulation (see Kabbalah). Another important source was the thirteenth-century theologian Ramon Llull, who stressed a method of achieving universal knowledge through combinations of letters signifying fundamental categories of reality (see Llull, R. §2).

2 Artificial schemes

During the seventeenth century, there occurred an explosion of interest in universal language schemes, conceived for the first time as systems of artificial signs or 'characters' constructed by human beings as a means of overcoming the limitations of natural languages. The causes of this newfound fascination with universal languages are complex. Clearly, a role must be assigned to the growing importance of vernacular languages and the decline of Latin as a shared medium of commerce, scholarship and diplomacy. An increase in millenarian religious sentiment, particularly in England, renewed the call for a recovery of the Adamic language. Finally, and most importantly, there was a growing recognition of the significance of language as a factor in the acquisition of scientific knowledge.

One of the earliest and most influential statements on the topic was Francis Bacon's reference in *The Advancement of Learning* (1605 II: ch. 16) to languages such as Chinese, whose users 'write in characters real, which express neither letters nor words in gross, but things or notions'. To many seventeenth-century thinkers, Chinese provided a model of what a universal language might be: a single set of characters that could be pronounced differently in different languages, but which when written would offer a shared basis for understanding. Implicit in Bacon's remark, however, was a further idea that pointed toward the scientific value of such a language. In his *New Organon* (1620 I: aph. 59), Bacon complained of how words commonly obscure 'the true divisions of nature'. It was a short step from this to the idea that these 'true divisions' might be better represented in a language composed of 'real characters', which directly expressed 'things or notions' (see Bacon, F. §§4-5).

Most early proponents of artificial language schemes stressed the practical value of their inventions as instruments of communication. Their works were primarily attempts to devise a system of writing, modelled variously on Chinese characters, cryptographic codes or shorthand notation, whereby synonymous words in different languages would be represented by a common sign. It was not long, however, before the more ambitious idea of a

'philosophical language' took hold. In a 1629 letter to Marin Mersenne, Descartes had already expressed scepticism concerning the usefulness of artificial languages of the first sort. However, he went on to postulate another kind of language in which ideas would be represented so clearly that errors of judgment would be 'almost impossible'. To realize such a language, all of our thoughts would first have to be given a proper order 'like the natural order of the numbers'; and this presupposes the 'true philosophy', by which the analysis and ordering of thoughts would be carried out. Although Descartes pursues the plan no further, he is optimistic that 'such a language is possible and that the knowledge on which it depends can be discovered'.

A philosophical language of the sort envisioned by Descartes is described in Mersenne's *Harmonie Universelle* (1636) and was pursued in many later works, culminating in George Dalgarno's *Ars Signorum* (1661) and John Wilkins' *An Essay Towards a Real Character and a Philosophical Language* (1668). Such schemes typically consisted of two parts: a system of categories summarizing the 'true divisions' of nature, and a set of characters suitable for representing these categories and the elements within them. Although informed by the discoveries of seventeenth-century science, the first part of the scheme was strongly indebted to the systems of categories propounded by Aristotle and medieval philosophers. In his *Essay*, Wilkins begins with forty genera (classified as transcendentals, substances, quantities, qualities, actions and relations), each of which he subdivides into its 'proper differences and species'. He then proposes two ways of representing the composition of concepts from their respective genus, difference and species: (1) a real character, or system of ideographic signs formed from combinations of vertical and horizontal lines; (2) a speakable philosophical language, consisting of novel combinations of syllables, consonants and vowels. In both cases, additional signs must be added to play the role of particles underwriting the grammatical structure of the language.

3 Leibniz

The idea of a universal language received its final significant development in the seventeenth century in the writings of Gottfried Wilhelm Leibniz. Although indebted to the efforts of Dalgarno and Wilkins, Leibniz criticizes these authors for their reliance on what he sees as an arbitrary number of basic categories. Harking back to Descartes, Leibniz locates the key to a philosophical language in an analysis by which every concept would be broken down into its simplest elements, the 'alphabet of human thoughts'. With these simples identified, and appropriate characters assigned to each, we would, in effect, possess the Adamic language: one in which the structure of every character perfectly mirrors the structure of reality.

Leibniz's plans for a universal language are among the most ambitious devised; in practice, however, they met with limited success. Early on, he recognized that an analysis of concepts into ultimate simples lies beyond the power of the human mind. What we are left with, then, are classificatory systems, like that of Wilkins, which represent our best attempts to order reality as we conceive it. Leibniz's greatest achievement in the area lies in his *specieuse générale* or 'general science of forms', a collection of calculi designed to support the formalization of reasoning in every branch of knowledge. Anticipating twentieth-century developments in logic and methodology, Leibniz's studies represent one of the enduring legacies of the universal language movement (see Leibniz, G.W. §10).

Universalism in ethics

The claim that ethical standards or principles are universal is an ancient commonplace of many ethical traditions and of contemporary political life, particularly in appeals to universal human rights. Yet it remains controversial. There are many sources of controversy. Universalism in ethics may be identified with claims about the form, scope or content of ethical principles, or with the very idea that ethical judgment appeals to principles, rather than to particular cases. Or it may be identified with various claims to identify a single fundamental universal principle, from which all other ethical principles and judgments derive. These disagreements can be clarified, and perhaps in part resolved, by distinguishing a number of different conceptions of universalism in ethics.

1 Form and scope: principles for everybody

One distinctive understanding of universalism in ethics is that ethical principles are principles *for everybody*. They prescribe obligations for everybody, define rights for everybody, list virtues for everybody. The most minimal version of ethical universalism is a claim about the *form* of ethical principles or standards. It is the claim that ethical principles hold for all and not merely for some, that is, for everybody without exception.

Those who hold that ethical principles are universal in form often disagree about their *scope*, that is to say about which beings comprise ‘everybody’. Plato’s character Meno tells Socrates that there are quite different virtues for men and women, for boys and girls, for old men and slaves (*Meno* 71e). On the other hand, Cicero famously asserted that ‘there will not be different laws at Rome and at Athens, now and in the future, but one eternal and unchangeable law for all nations and all times’ (*De Republica* III, 33) (see Cicero, M.T. §2); and St Paul proclaimed that ‘there is neither Jew nor Greek, there is neither bond nor free, there is neither male nor female: for ye are all one in Christ Jesus’ (Galatians 3:28). One very influential understanding of universalism in ethics, shared by many religions, by the natural law and liberal traditions, and by many others, is the contention that ethical principles are universal in form and cosmopolitan in scope, in that they hold for all humans.

However, any cosmopolitan view of the scope of ethical principles must note that living up to obligations, virtues and even some rights is impossible for human beings who lack mature capacities for action. Neither infants nor small children, neither the retarded nor the senile, can be held accountable for carrying out obligations, living virtuously or exercising certain rights, such as political rights. Yet humans who lack these capacities might have other rights, for example, to care and protection. Those who can suffer but not act can be moral patients but not moral agents, possessing some rights, but not the full range of obligations, virtues or rights. The scope of different sorts of principles of universal form will evidently have to vary (see Moral agents; Responsibility).

Many think that the scope of some ethical principles is more-than-cosmopolitan. Jeremy Bentham famously declared that the criterion of moral standing was ‘not, Can they *reason*? nor, Can they *talk*? but Can they *suffer*?’ (1789: 412, footnote; original emphasis); Hindus and Buddhists too extend moral concern beyond humankind; some environmentalists extend concern not only to nonhuman animals, but to plants, even to species and habitats (see Animals and ethics; Bentham, J. §2; Duty and virtue, Indian conceptions of; Environmental ethics; Moral standing §2-3).

Other advocates of principles of universal form join Meno in holding that their scope is less-than-cosmopolitan. For example, communitarians (who sometimes describe themselves as *rejecting* universal principles) advocate principles of universal form whose scope is restricted to particular communities (see Community and communitarianism); some virtue ethicists hold similar views (see Virtue ethics §5).

2 Content: formal principles or uniform requirements?

A second conception of universalism in ethics emphasizes the content as well as the form and scope of principles. Principles which hold for everybody will prescribe or recommend the same for everybody (same obligations, same rights, same virtues and so on). Advocates of universal principles see this as a merit: they see equality of requirement and entitlement as ethically important (see Equality §3). For example, discussions of universal human rights emphasize not only that all humans have rights, but that they all have the same rights.

Two objections are commonly raised. The first is that principles which prescribe the same for all will be abstract

and general, so provide too little guidance. The second is that they will be too demanding and specific, prescribing with senseless and heartless uniformity for differing cases and situations. On this account, universal principles are either too formal and minimal or else too uniformly demanding. Evidently the two criticisms cannot both be true of one and the same universal principle. If a principle is so abstract that it provides no practical guidance, then it will not prescribe rigid uniformity of action; conversely, if it prescribes with rigid uniformity it will not fail to guide action.

The charge that ethical principles which prescribe the same for all abstract from differences between cases is true, but not damaging. No principle of action - whether of universal or non-universal form, whether of cosmopolitan or lesser scope - can prescribe with total specificity; even very explicit principles abstract from many circumstances. It follows that principles of action can always be satisfied in varied ways. A principle such as ‘Tell the truth’ does not prescribe what we must say to whom or when; a principle such as ‘Pay your debts’ does not determine the means or manner of repayment. Principles of action, including ethical principles, *constrain* action or entitlements, rather than picking out a single, wholly determinate line of action. Abstract principles can therefore guide action yet allow for flexible interpretation or application that takes account of differences between cases. So an ethics of universal principles can readily avoid both barren formalism and doctrinaire rigorism.

3 Universalism and particularism: principles and judgment

Since universal ethical principles are always to some extent abstract or indeterminate they must be supplemented by *judgment* in selecting among possible implementations. This point is recognized, indeed stressed, by advocates of universal principles. Kant (1781/1787), for example, insisted that there cannot be complete rules for judgment, and that principles cannot entail their determinate applications, which require judgment (see Kant, I. §12).

The serious disagreement lies not between those who think that ethics needs *only* principles and those who think it needs *only* judgment of particular cases, but between those who think principles and judgment are both needed and those who believe that judgment alone will be enough. The deepest opposition to any sort of ethical universalism comes from ethical particularists who hold that unmediated apprehension of particular cases can guide ethical life. Ethical particularists seek to anchor ethical judgment in perception of and responsiveness to the particular, in attentiveness to the case at hand, in the salience of the personal relationship and its claims (see Friendship; Impartiality §4). They usually hold that ethical life revolves around character and virtue. The most radical cast doubt on the very conception of following a rule or principle; the less radical cite the issues of §2 as evidence that an ethics of rules and duties is inadequate (see Moral particularism).

Both ethical particularists (who appeal only to judgment) and universalists (who argue that judgment is used in combination with principles) have found it difficult to explain how judgment works. Some particularists describe it as analogous to perceiving or attending or to the exercise of a craft skill. Some universalists see judgment as the skill of identifying acts that fall within the constraints set by a plurality of principles (see Moral judgment).

4 Fundamental principles: ‘golden rules’

Other conceptions of universalism in ethics combine views of the form, scope and sameness of content of principles with ambitious claims that a single fundamental universal principle provides the basis for all derivative ethical principles and ultimately for ethical judgment of particular cases.

Often the proposed fundamental principle is a version of a ‘golden rule’. Variously formulated golden rules are found in Hindu and Confucian sacred texts, and in many other traditions, including natural law and popular ethical debate. One well known golden rule is Christian with Jewish antecedents: ‘Do unto others as you would that they should do unto you’ (for specific formulations see Matthew 7:12, Luke 6:31; for antecedents Tobias 4:15). Others are prohibitions rather than injunctions, such as ‘Do not do unto others what you would not have them do unto you’.

These would-be foundational principles have been criticized for linking ethics too closely to agents’ desires or consent. Why should willingness to be on the receiving end of like action make it permissible? If masochists are willing to suffer others’ sadism, would that make sadism right? More generally, can acceptance of being on the receiving end of like action legitimate anything?

This problem can be overcome only by building additional constraints or complexities into the idea of considering what one would desire or consent to when putting oneself into another's shoes. This has been attempted in various principles, which are first cousin to golden rules, that have been influential in secular work in ethics. Most famously J.S. Mill asserted, in *Utilitarianism* (1861), that 'in the golden rule of Jesus of Nazareth, we read the complete spirit of the ethics of utility'. The link Mill draws between utilitarianism and golden rules arises only if agents consider not what they as individuals would want if on the receiving end, but what they if taking account of all others' desires would want if on the receiving end. Only then can a golden rule reflect everybody's desires, and so be thought of as aiming at the greatest happiness (see Utilitarianism; Mill, J.S. §10).

Other approaches of this sort have recently been advocated by P. Singer (1972), R.M. Hare (1975) and A. Gewirth (1987), each of whom recognizes affinities as well as differences between his proposal for the foundations of ethics and traditional golden rules. For example, Gewirth suggests that a rational golden rule would read 'Do unto others as you have a right that they do unto you', while Hare advocates a universal prescriptivism by which the fundamental criterion for ethical judgment is that agents be willing to universalize their judgments, that is extend them to all situations identical in their universal properties (see Prescriptivism; Hare, R.M. §§1-2). There has been much discussion of the plausibility of these proposals, which generally reject the emphasis traditional golden rules give to what one would have if the particular victim reciprocated, and introduce some reference to what one would want if one's own principle were to be universally adopted or if one's desires took account of others' desires. These writers advocate a strong form of ethical universalism: not merely do they defend a single fundamental ethical principle, but they insist that it refer to the desires that all hold, or ought if rational to hold.

5 Fundamental principles: Kantian universalizability

An alternative conception of universalism in ethics rejects golden rules and seeks to anchor all ethical justification in a more formal fundamental universal principle, which does not refer to desires or consent to fix the content of ethics. The most famous and most ambitious attempt to go further is Kant's 'categorical imperative', of which the best known version runs: 'Act only on that maxim through which you can at the same time will that it should become a universal law' ([1785] 1903: 421). Kant claims to show that 'all imperatives of duty can be derived from this one imperative as their principle' (421). He insists that in such derivations no reference be made either to anyone's happiness or desires, consent or agreement, and that the categorical imperative is not a version of a golden rule (which he dismisses as trivial, 430, footnote). Kant's views have been influential: a German scholar recently commented that 'Kant succeeded with his objection almost in invalidating the golden rule and disqualifying it from future discussion in ethics' (Reiner 1983: 274).

English language philosophy has been less convinced that Kant undermined golden rule approaches. J.S. Mill was neither the first nor the last to think that Kant's claim to derive all principles of duty from the categorical imperative was complete nonsense. He wrote of Kant

> when he begins to deduce from this precept any of the actual duties of morality, he fails, almost grotesquely, to show that there would be any contradiction, any logical (not to say physical) impossibility, in the adoption by all rational beings of the most outrageously immoral rules of conduct. All he shows is that the *consequences* of their universal adoption would be such as no one would choose to incur.
>
> (1861: 207; original emphasis)

There has been widespread scepticism about Kant's supposed claim to show that 'immoral rules of conduct' are self-contradictory. However, he in fact makes the more circumspect *modal* claim that we should not act on principles which we *cannot* simultaneously 'will as universal laws'. An example of such a principle is that of false promising. Kant holds that false promisers who try (incoherently) to will false promising as a universal law thereby will the destruction of the very trust on which their own attempts to promise falsely must rely. Hence when we try to act on such principles Kant holds that

> we in fact do not will that our maxim (principle) should become a universal law - since this is impossible for us - but rather that its opposite should remain a law universally: we only take the liberty of making an *exception* to it for ourselves (or even just for this once).
>
> ([1785] 1903: 424; original emphasis)

In 'deriving' an 'actual principle of duty' from the categorical imperative, Kant takes it that agents not only seek principles of universal form and cosmopolitan scope which prescribe the same for all, but shun any principles which cannot be 'willed for all'. Kantian justifications of such principles, unlike golden rule justifications, do not appeal to either the desires, the happiness or the acceptance of those on the receiving end, nor indeed to actual or hypothetical desires of any or of all agents. The distinctive modal character of Kantian universalizability is its appeal to what *can be willed for all* (rather than to what *actually is* or *hypothetically would be willed by all*). It remains a matter of considerable controversy whether a strictly Kantian approach can be used to construct an account of specific principles of duty, virtue or entitlement, or whether it is indeed too formal and minimal to sustain these derivations.

Universals

In metaphysics, the term 'universals' is applied to things of two sorts: properties (such as redness or roundness), and relations (such as kinship relations like sisterhood, or the causal relation, or spatial and temporal relations). Universals are to be understood by contrast with particulars. Few universals, if any, are truly 'universal' in the sense that they are shared by all individuals - a universal is characteristically the sort of thing which some individuals may have in common, and others may lack.

Universals have been conceived to be things which enable us intellectually to grasp a permanent, underlying order behind the changing flux of experience. Some of the gods of ancient mythologies correspond roughly to various important underlying universals - social relations for instance, as for example if Hera is said to be the goddess of Marriage and Ares (or Mars) is said to be the god of War. Many traditions, East and West, have dealt with the underlying problem which generates theories of universals; nevertheless the term 'universals' is closely tied to the Western tradition, and the agenda has been set largely by the work of Plato and Aristotle.

The term often used in connection with Plato is not 'universals' but 'Forms' (or 'Ideas', used in the sense of ideals rather than of thoughts), the term 'universals' echoing Aristotle more than Plato. Other terms cognate with universals include not only properties and relations, but also qualities, attributes, characteristics, essences and accidents (in the sense of qualities which a thing has not of necessity but only by accident), species and genus, and natural kinds.

Various arguments have been advanced to establish the existence of universals, the most memorable of which is the 'one over many' argument. There are also various arguments against the existence of universals. There are, for instance, various vicious regress arguments which derive from Aristotle's so-called 'third man argument' against Plato. Another family of arguments trades on what is called Ockham's razor: it is argued that we can say anything we need to say, and explain everything we need to explain, without appeal to universals; and if we can, and if we are rational, then we should. Those who believe in universals are called Realists, those who do not are called Nominalists.

1 Sources in ancient mathematics and biology

Plato looked to mathematics as a model to find ideal 'forms' which can be grasped by the intellect and which we find to be imperfectly reflected in the world of the senses. Moral and political ideals too, Plato thought, are reflected only very imperfectly in the world of appearances. Aristotle's conception of universals was tailored to fit not mathematics but biology. Individual animals and plants fall into natural kinds, or species, such as pigs or cabbages. Various different species, in turn, fall under a genus.

Universals impose a taxonomy on the plurality of different individuals in the world. Regularities in the world can then be understood by appeal to the universals, or species, under which individuals fall, explaining why pigs never give birth to kittens, for instance, and in general why each living thing generates others of its kind.

Plato conceived of universals as transcendent beings, *ante rem* in Latin ('before things'): the existence of universals does not depend on the existence of individuals which instantiated them. This is a natural thought if your model of universals lies in mathematics: geometrical truths about circles, for instance, do not depend on the existence of any individuals which really are perfectly circular. Aristotle, in contrast, held a theory of universals as immanent beings, *in rebus* ('in things'): there can be no universals unless there are individuals in which those universals are instantiated. This is a natural thought if your model of universals lies in biology: a species cannot exist, for instance, if there are no animals of that species. Thus, one of the key distinctions between Plato's transcendent and Aristotle's immanent realism is that the Platonist allows, and Aristotle does not allow, the existence of uninstantiated universals (see Aristotle §15; Plato).

2 Samenesses and differences

When a property is shared by two individuals, there is something which is in or is had by both. But it is in a quite distinctive sense that one universal can be 'in' two distinct individuals. An individual person may be 'in' two places at once if, for instance, their hand is in the cookie jar and their foot is in the bath. But a universal is 'in'

distinct individuals in a way which does not mean that there is one part of the universal in one thing and a distinct part of it in another. Thus, a universal is said to be the sort of thing which can be wholly present in distinct individuals at the same time: a person cannot be wholly present in two places at once, but justice can.

Some draw a distinction between certain special properties and relations which qualify for the label ‘universals’, and other properties and relations which do not. It is suggested that, whenever something is true of an individual (whenever a description can truly be predicated of an individual), then there is always a ‘property’ which that individual may be said to have. On this view, a ‘property’ is just a shadow of a predicate, whereas a genuine universal is something more. A genuine universal has to be something which is literally identical in each of its instances. Alternatively, the sorts of ‘properties’ which are just shadows of predicates are sometimes construed as set-theoretical constructions of various sorts, as for instance if we say that the ‘property’ of redness is the set of actual red things, or of actual and possible red things. In this spirit it is now standard practice in mathematics to use the term ‘relations’ to refer just to any set of ordered pairs. Set-theoretical constructions are not, however, universals - or at least they are not to be confused with the universals which are the subject matter of traditional debates.

3 Arguments for and against

Various arguments have been advanced to establish the existence of universals, the most memorable of which is the ‘one over many’ argument. Although it is memorable, there is little consensus on just how this argument works. Very roughly, it begins with an appeal to the manifest fact of recurrence, the fact that, as it says in the biblical text of *Ecclesiastes* (1: 9), ‘What has been is what will be, and what has been done is what will be done; and there is nothing new under the sun’. There are many things, and yet they are all in some sense just the very same things over and over again. From this manifest fact of recurrence, the argument purports to derive the conclusion that there are universals as well as particulars.

There are also various arguments against the existence of universals. One family of such arguments derives from Aristotle’s so-called ‘third man argument’ and is designed to demonstrate that Plato’s Theory of Forms entails an unacceptable infinite regress. Roughly, Plato’s problem is that he needs some relation to hold between the Form of Man and individual men before this Form can help to explain what it is that individual men have in common. So the theory would seem to call into being another Form, a third man, which is what the Form of Man has in common with individual men. This leads to an infinite regress, hence Plato’s Theory of Forms is unacceptable. Of course, Aristotle had only intended to demonstrate the nonexistence of Plato’s Forms, not of universals in general; but enemies of universals frequently advance related infinite-regress arguments against the existence of universals of any kind. Whatever you call the instantiation relation between particulars and universals, if you think of it as another universal then you are off on a regress, and this seems to count against any theory of universals.

Another argument against the existence of universals trades on what is called ‘Ockham’s razor’ - the principle that you should not postulate more entities when everything you want to explain can be explained with fewer (see William of Ockham §2). It is sometimes argued that everything you can explain with universals can be explained just as well without them. Things which superficially seem to refer to universals can, it is maintained, generally be rephrased in ways which make no apparent reference to universals - reference to universals can be paraphrased away. If we can do without universals, then obviously we should; when you supplement this Ockhamist argument with allusions to the interminable and unresolvable internecine conflicts among Realists over numerous details, you have an even stronger case against the existence of universals.

4 Nominalism and Realism

During the Middle Ages in Europe, universals played a focal role in the intellectual economy: many issues revolved around what became known as the problem of universals. Famously, a commentary by Boethius on Porphyry’s *Isagoge*, which in turn was intended as an introduction to Aristotle’s Categories, set very crisply but vividly and tantalizingly what came to be taken as a compulsory question in the Medieval pursuit of learning: whether genera and species are substances or are set in the mind alone; whether they are corporeal or incorporeal substances; and whether they are separate from the things perceived by the senses or set in them (Boethius *c*.510; Spade 1994). The initial problem for many was not one of deciding whether there are any universals, but of choosing between Plato and Aristotle and then fine-tuning further details.

Later in the Middle Ages, however, a growing number of philosophers and theologians became more and more impressed by arguments against the existence of universals. They began to adopt the position called 'Nominalism' which was opposed to all the various forms of Platonic or Aristotelian Realism. According to Nominalists like Abelard and Ockham, the only thing which distinct individuals share in common is a common name, a label which we choose to apply to each of those individuals and not to others.

Nominalistic claims were echoed by many of the champions of the modern sciences as they emerged at the end of the Middle Ages. It was standardly said to be granted on all hands that all existing things are merely particular. Being assumed as granted on all hands, it was not up for debate, and so the problem of universals, explicitly so described, settled into the shadowy background of scientific and philosophical discussion. For example, an archaeologist of ideas might argue that, in Kant, the problem of universals is really alive and working very hard in the background, playing a role in discussions on almost every topic that arises. Nonetheless the problem of universals, under that name or any clear equivalent, is not featured on Kant's explicit agenda. Kant speaks of intuitions and concepts in ways which have some relation to the old problem of particulars and universals, but more has shifted than just the labels. Hence the problem of universals has received little attention across a great span of philosophical history, right through to twentieth-century philosophy in France and Germany (see Nominalism §2; Realism and antirealism).

5 Frege exhumes universals

In the twentieth century, the problem of universals has re-emerged under its familiar name, accompanied by more or less the same guiding illustrations used by Plato and Aristotle. This rebirth has occurred in the tradition of analytic philosophy, notably in the work of Frege, Russell, Wittgenstein, Quine and Armstrong.

A new twist to the theory of universals can be traced to groundbreaking work by Frege on the nature of natural numbers in his *Grundlagen der Arithmetik (The Foundations of Arithmetic)* (1884). As for Plato, so too for Frege, Russell and others in recent times, advances in mathematics have been the source of a philosophical focus on the problem of universals. Frege's analysis of natural numbers (1, 2, 3,…) proceeded in three very different stages (see Frege, G. §9).

In the first stage of his analysis of numbers, Frege introduced the idea that numbering individuals essentially involves not the attribution of properties to individuals but, rather, the attribution of properties to properties. To illustrate: when asked 'How many are on the table?', Frege notes that there will be many different possible answers, as for instance (1) 'Two packs of playing cards' or (2) '104 playing cards'. The metaphysical truth-makers identified by Frege for these two sample answers are (1) that the property of being a pack of playing cards on the table is a property which has the property of having two instances, and (2) that the property of being a playing card on the table is a property which has the property of having one hundred and four instances. In general, natural numbers number individuals only via the intermediary of contributing to second-order properties, or properties of properties, namely properties of the form 'having *n* instances'. Like Kant, Frege speaks of concepts (*Begriffe*) rather than of 'universals'. Yet Frege's concepts are definitively not private mental episodes, but are thoroughly mind-independent, more like Plato's Forms than Aristotelian universals.

In the second stage of his analysis of numbers, Frege gives a very new twist to the theory of universals. He argues that the nature of universals, or concepts, is such as to make it impossible in principle ever to refer to a universal by any name or description. Thus for instance, in saying 'Socrates is wise', the universal which is instantiated by Socrates is something which is expressed by the whole arrangement of symbols into which the name 'Socrates' is embedded to yield the sentence 'Socrates is wise'. Suppose you were to try to name this universal by the name 'wisdom'. Then, compare 'Socrates is wise' with the concatenation of names - 'Socrates wisdom'. The mere name 'wisdom' clearly leaves out something which was present in the attribution of wisdom to Socrates. Hence a universal cannot be referred to by a name.

Thus, a property can only be expressed by a predicate, never by a name or by any logical device which refers to individuals. Indeed, if we wish to attribute existence to universals, we cannot do so by the use of the same sort of device (the first-order quantifier) which is used to attribute existence to individuals. Thus, for instance, from 'Socrates is wise' we may infer 'There exists something which is wise', and 'There exists something which is Socrates':

$(\exists x)(\text{wise}(x))$, and
$(\exists x)(x = \text{Socrates})$.

Yet we may not infer that ‘There exists something which Socrates possesses’, or that ‘There exists something which is wisdom’:

$(\exists x)(\text{has}(\text{Socrates}, x))$, or
$(\exists x)(x = \text{wisdom})$.

Frege does, however, allow us to attribute existence to universals, using logical devices called higher-order quantifiers, which he introduced in his *Begriffsschrift* (1879). That is, we can infer from ‘Socrates is wise’ to ‘There is somehow such that: Socrates is that-how’:

(E*f*)(*f*(Socrates)).

But although there is somehow that Socrates is, this does not entail that there is anything which is the somehow that Socrates is: universals (concepts) can only have second-order existence, not first-order existence.

For Frege, numbering things essentially involved attribution of properties to properties. So the sorts of things being attributed are not the sorts of things which can be named. Yet, Frege argued, numbers can be named - numbers are abstract individuals, he says, objects not concepts. Hence the third stage of Frege’s analysis of numbers consists in the attempt to find individuals - objects - which could be identified with the numbers. It was this stage of the analysis which resulted in the emergence of modern set theory. For every property, Frege argued, there is a corresponding individual: the extension of that universal, the set of all the things (or all the actual and possible things) which instantiate that universal. Thus, for instance, corresponding to the property of being a property which has two instances, there will be a set of sets which have two members. Modern mathematics has selected different candidates for identification with the natural numbers, but it has followed Frege hook, line and sinker with respect to the broad strategy of identifying numbers, and functions and relations, with sets.

Frege’s legacy has significantly changed the agenda for any theory of universals which, like Plato’s, aspires to do justice to mathematics. It leaves three courses open for exploration. One course is that charted by Quine (1953, 1960), of allowing the existence of sets but not of any other nameable things which might be called universals, nor of any of Frege’s higher-order, unnameable universals. Another course is that of allowing the existence of nameable things other than sets: this is a course charted, for example, by Armstrong (1978). A third course allows also the irreducible significance of higher-order quantification (Boolos 1975; Bigelow and Pargetter 1990).

Universals, Indian theories of

Indian philosophers postulated universals for two principal reasons: to serve as the 'eternal' meanings of words, upon which the eternality of language - in particular, the Hindu scriptures, the Veda - is based, and to account for why we conceive of things as being of certain types. However, universals were seen as problematic in various ways. How can something exist simultaneously in numerous individuals without being divided into parts? How can a universal, which is supposed to be eternal, continue to exist if all its substrata are destroyed? In what sense can a universal be said to 'exist' at all? Is a universal distinct from or identical with the individuals in which it inheres? In light of such difficulties, it is not surprising that certain other Indian philosophers - specifically Buddhist philosophers, who did not accept the doctrine of the eternality of the Veda - rejected universals and took up a nominalist stance. They held that general terms refer to mentally constructed 'exclusion classes', apohas. *The use of the term 'cow', for example, is grounded not on some positive entity common to all cows but on the idea of the class of things that are different from all things that are not cows. This proposal, which originated with Dignāga in the sixth century* AD*, was debated vigorously until the eleventh century.*

1 Universals as the meanings of words

The question of universals first arose in Indian philosophy with regard to language. In his commentary on Pāṇini's grammar of classical Sanskrit, Patañjali (second century BC) considers the thesis upon which the Hindu belief in the eternality of the Veda is grounded, that word, meaning and the connection between the two are 'eternal'. What would the meaning of a word have to be in order for it to be eternal? Presumably, not the individual thing or 'substance' (*dravya*), which is perishable, but the 'shape' or 'configuration' (*ākṛti*), which is common to many individuals. Although the *ākṛti* may be destroyed with one individual, it will continue to exist in others ((*Vyākarana*-) *Mahābhāṣya*, 1.1.1, 1962, vol. 1: 7). Here, *ākṛti* is not yet a universal in the sense of an abstract entity that makes various individuals members of a single class, but the visible form by which the members of a class are recognized. Patañjali also notes, however, that the 'substance', in the sense of the stuff out of which a thing is made, can also be considered eternal: the shape of a lump of gold may be altered in various ways, but the gold itself will remain the same. Thus, he settles on neither *ākṛti* nor *dravya* as the exclusive meaning of a word. Depending on the context, one or the other emerges as the meaning. In particular, when Pāṇini says (*Aṣṭādhyāyī* 1.2.58) that nouns may optionally take plural endings when they refer to a class - that is, one may say either 'the Brahman' or 'Brahmans' when referring to the class of Brahmans - he implies that the meaning of the word is the *ākṛti*. On the other hand, when he says (*Aṣṭādhyāyī* 1.2.64) that the plural form of a word is really an abbreviation for the same word iterated several times, he seems to have the *dravya* - even in the sense of the concrete individual - in mind (*Mahābhāṣya* 1.1.1, 1962, vol. 1: 6).

Patañjali records the opinions of other ancient grammarians (*Mahābhāṣya* 1.2.64, vol. 1: 242-). Vājapyāyana held that a word must express the *ākṛti*, because the rules of *dharma* apply universally and not just to specific things. When the law forbids the killing of a Brahman, it means that one should not kill *any* Brahman, not just a particular Brahman! Moreover, words evoke general notions. When someone says 'cow', we do not think of a particular white or black cow; we just think 'cow' in general. Vyāḍi, on the other hand, pointed out that actions can be carried out only with reference to individuals. An injunction that one should sacrifice a certain animal means that one should sacrifice an individual animal of a certain type; one could hardly carry out the action with regard to the entire species! Also, it would seem that nouns could have number and gender only if they referred to individuals. Finally, Vyāḍi wonders how the *ākṛti* can be fully present in many individuals simultaneously. Vājapyāyana responds that it is possible in the same way that it is possible for the sun to shine in many places or for Indra to be simultaneously present at many sacrifices.

This same debate is played out in the *Mīmāṃsāsūtra* (1.3.30-5), where the issue is decided in favour of the *ākṛti*, which is now explicitly declared by the commentators to be a universal (*sāmānya*). It is still recognized, however, that in certain contexts, such as sacrificial injunctions, words indirectly refer to individuals; for universals have individuals as their substrata (*Mīmāṃsāsūtrabhāṣya*, 1981, vol. 2: 266-7). The teaching of the influential Bhāṭṭa school of Mīmāṃsāwas that the universal is the primary meaning of a word, while the individual is the secondary or metaphorical meaning to which one resorts when an expression cannot be construed literally (for example, in a sacrificial context) (see MīmāṃsāČsect;Čsect;2-3). In the *Nyāyasūtra* all three items - individual (*vyakti*),

universal (*jāti*) and configuration (*ākṛti*) - are declared to be jointly the meaning of a word (2.2.66). The individual alone cannot be the meaning, because we never apprehend a mere individual, an individual which is not of a certain kind; the configuration alone cannot be the meaning, because things having the configuration of, say, a cow are not necessarily cows (for example, images of cows); and the universal by itself cannot be the meaning, because one does not apprehend the universal without perceiving an individual having a certain configuration. Thus, all three together comprise the meaning of a word, one becoming dominant, the others subordinate, in different circumstances. When one, for example, intends the distinctness of the referent from other things - as in the sentence 'Wash *that* cow' - then the *vyakti* becomes predominant; when one intends to include many things together - as in the sentence 'One should not kill a cow' - the *jāti*, or universal, becomes predominant.

2 The Vaiśeṣika theory

In the literature of the Hindu Vaiśeṣika school of natural philosophy the question of universals is approached from the standpoint of ontology. The *Vaiśeṣikasūtra* lists universals (*sāmānya*) as one of the six principal categories of things (1.1.4) (see Nyāya-Vaiśeṣika §§4-5). Their existence is known from the fact that we have common notions and terms; there must be something identical existing in different individuals that causes us to conceive of them in the same way and refer to them by the same word. Universals can be arranged in hierarchical series: animality is higher than cowness, while substantiality is higher than animality. The highest universal of all, which stands at the pinnacle of every such series and falls under no other universal, is 'existence' (*sattā*). Universals below existence can be construed either as functions of generality or particularity (*Vaiśeṣikasūtra* 1.2.3). Cowness causes us to group together all cows in one class, but also separates them from other animals. Moreover, cowness functions as a particularity with respect to universals of wider scope, such as animality: it distinguishes a certain type of animal within the genus of animals.

All cows, all animals - in general, all substances, qualities and actions - are considered 'existents' (*sat*) due to the fact that the universal 'existence' resides in them (*Vaiśeṣikasūtra* 1.2.7). Universals themselves, however, are not existents. While it can be said of a universal that it 'is' (*asti*) in so far as it possesses intrinsic nature (*svarūpa*), and while it can be known and be named, it does not exist in the same concrete sense as substances, qualities and actions: it is 'not expressible by the word *artha* ['thing']' (*Padārthadharmasaōgraha*, 1971: 49; *Vaiśeṣikasūtra* 8.2.3). In a way similar to Aristotle's account, then, 'being' does not apply univocally to all categories in Vaiśeṣika (though it should be noted that Aristotle does not consider 'universal' a category; thus, it can also be said that Vaiśeṣika differs from Aristotle in considering 'being' to apply univocally to substances, qualities and actions) (see Aristotle §7). Nor is there a universal 'universalness' that inheres in all universals; for that would lead to a 'third-man' type of regress.

Qualities are not universals in Vaiśeṣika thought. The red that occurs in a particular object is itself a particular. There is, however, a universal redness that is common to all particular occurrences of red. This contrasts with the view found in grammatical and Mīmāṃsāliterature that qualities are repeatable types: it is the *same* quality red that occurs in all things red.

It is evident that the universals of Vaiśeṣika and Nyāya - the Hindu school devoted primarily to logic and epistemology, which adopted the metaphysics of Vaiśeṣika - resemble Aristotelian universals more than Platonic forms (see Universals §1). They are neither substances nor causes of substances; they are neither essences nor responsible for the natures of things; nor are they ideal entities - a point that distinguishes them from both Platonic and Aristotelian universals. Rather, a universal simply endows an individual thing, whose nature derives from other causes, with the capacity to give rise to a certain notion such as 'cow' or 'pot', a capacity that it shares with other individuals. Moreover, although universals are quite distinct from the individuals in which they inhere - for they are eternal and 'common', while individuals are perishable and particular - they are never cognized, nor in any clear sense exist apart from them.

Other thinkers, however, conceived of universals as being more intimately related to individual substances. The grammarian Bhartṛhari (fifth century AD) held universals to be causally involved in the formation of substances; they activate the material causes that bring about the substances in which they inhere. He noted this phenomenon in the production of artefacts, much as Aristotle did: the artisan is guided by the universal (for Aristotle, read 'substantial form') in producing an object of a certain type, which will in turn exhibit the universal (*Vākyapadīya* 3.25-7). Ultimately for Bhartṛhari, who was a monist (Advaitin), both universals and individual substances are

creative potencies (*śakti*) within Brahman, different ways in which it limits itself as it becomes the empirical world. Universal and individual, that is, are merely different aspects of the finite self-expressions of Brahman, hence they are identical (*Vākyapadīya* 3.22-3, 32-3; 1.1-4). This metaphysical doctrine can be seen as a reflection of the linguistic one that words refer to both universals and individuals.

The Mīmāṃsāphilosopher Kumārila (seventh century AD) also held that the universal and the individual form a unity; for we do not cognize a universal as externally related to the individual. We do not cognize the universal 'cowness' as existing *in* the cow, rather we cognize the individual *as being* a cow (*Ślokavārttika*, 'Pratyakṣa' 141-2). The fact that individual and universal never exist apart from each other also bespeaks their identity. Furthermore, Kumārila held that one cannot make sense of the relation of 'inherence' (*samavāya*), by which Nyāya and Vaiśeṣika philosophers believed the universal and individual to be related. If one asks how *samavāya* itself is related to each of the terms it relates together, a regress ensues. Thus, according to Kumārila, who was a realist and a pluralist, the world is populated by numerous concrete entities that are both universal and particular in nature (*Ślokavārttika*, 'Ākṛti' 5-6, 59-65). A similar view was expressed by Jaina philosophers: universal and particular are neither absolutely different nor absolutely identical.

Jainas also held the distinctive doctrine of two types of universals, horizontal (*tīryaksāmānya*) and vertical (*ūrdhvatāsāmānya*). The former account for the various types of things that exist at the same time - cows, horses, and so on; the latter account for the identity of individual substances through time, that is, they enable us to recognize the various stages of a substance as the same thing.

One of the peculiarities of the Indian discussion of universals is that all those who believed in the reality of universals held them to be objects of perception; indeed, to be real and to be an object of perception were nearly the same in classical Indian philosophy. To say that universals are objects of thought would have been to say that they are mental constructs and therefore unreal. The latter view was in fact held by Buddhist philosophers (see §3). A theory of universals as real entities cognized by a process of mental abstraction was never achieved. Nyāya, Vaiśeṣika and Mīmāṃsāphilosophers argued that universals are objects of perception because their cognition occurs simultaneously with sense organ-object contact. Even when encountering a thing for the first time - say, a camel - one is able to *see* that it is an entity of a certain type, different from other kinds of entities one knows. One never perceives something that is completely particular in nature and devoid of any general character.

3 Controversies

In the face of the Buddhist denial of the reality of universals, Hindu and Jaina philosophers were compelled to develop more rigorous arguments for their existence. The most common argument was simply that distinct cognitions must have distinct causes. We have, besides the cognition of something as an individual, a cognition of it as a member of a certain class. There must be some real basis for the latter, in the same way that, when we cognize something as blue, there is some real basis of the cognition other than the individual substance itself, namely the quality blue (*Nyāyavārttika* 2.2.64, 1985: 667). Nor can the cognition of an individual as possessing a general character be based on a similarity between it and other individuals. Cows are in certain ways similar to each other, but in important respects also different; and almost to the same extent that there is a similarity between cows, there is a similarity between cows and horses, yet we do not call a horse a cow! Moreover, similarity would merely give rise to the notion that various things are 'like' each other, not that they are the same thing. If universals were not real, it was also argued, inference and reasoning, which are based on the observation of general traits, would not be valid means of knowledge. The Nyāya philosopher Udayana (eleventh century) contended that universals must be postulated to explain the necessity and uniformity of causal relations, such as the fact that not just this bit of milk will now produce yoghurt, but any portion at any time.

One problem that universal theorists had to face was whether a universal exists wholly in an individual or only partially. If wholly, then it would only be in that individual and could not also exist in others. If only a part of the universal existed in each individual, then it would not be one thing common to all (compare Plato's *Parmenides* 131a-e). The standard response to this dilemma was simply to stress that the property of existing completely in each of a class of individuals is one of the things that distinguishes universals from other categories. As the Nyāya philosopher Uddyotakara (sixth century) puts it: a universal is not a whole comprised of parts, nor a collection of many things, thus it is not really proper to put the question about whether it exists 'wholly' or 'partially' in something (*Nyāyavārttika* 2.2.64, 1985: 669).

What happens to a universal if all its individual substrata perish? It cannot cease to exist, for it is eternal; yet it is never perceived independently of its substrata either. Nyāya-Vaiśeṣika philosophers held that during periods of cosmic dissolution (*pralaya*), when there are no individuals at all, universals continue to exist in an unmanifest state - in so far as they can be said to 'exist' at all. Otherwise, some (for example, Jayantabhaṭṭa) held that when all the individuals of a particular universal are destroyed, universals continue to inhere in other individuals. That is to say, cowness (along with every other universal) is present in all things, even non-cows, and so will still be located in individuals even when cows have died out; but it is *perceived* only in cows (*Nyāyamañjarī*, 1983, vol. 2: 36-7). In such doctrines one sees a tendency to favour the notion that universals exist only *in rebus*. There were even philosophers who held that during *pralaya* universals continue to exist by virtue of inhering in individuals in other universes! Perhaps only Bhartṛhari would have been sympathetic to the Western medieval view that universals are *ante res*, in so far as they are eternal potencies within Brahman.

Finally, there is the matter of *upādhis*, general traits that are not universals. Nyāya-Vaiśeṣika philosophers wanted to deny that such terms as 'cookness' or 'servantness' refer to real, objective universals. Being a cook or a servant is not natural to a person; one becomes a cook or servant only when one comes to perform the actions appropriate to a cook or servant. Universals, however, are supposed to inhere permanently in their substrata from the moment of origin. Similarly, several men carrying umbrellas can be grouped together conceptually, but that will not be due to the presence of a universal in them. Thus, a distinction was made between general terms that are based on real universals and general terms that are based on inauthentic, nominal properties. Buddhists used this point to their own advantage: if some general terms are based on inauthentic, nominal properties, why not all?

The Buddhist critique of universals was initiated by Dignāga (sixth century) and continued by Dharmakīrti (seventh century), Śāntarakṣita (eighth century) and other thinkers until the eleventh century. An often-quoted verse of Dharmakīrti charges that the concept of universals is beset with a plethora of difficulties: when an individual arises in a particular place, the universal cannot move to where it is and unite with it, for a universal is without motion; nor could it have been present there all along, for then the empty space would have been cognized as falling under the universal. It is also absurd to think that a universal could join with an individual after it has arisen, since the individual would exist for a moment without any universal inhering in it (*Pramāṇavārttika*, 'Svārthānumāna' 152-3). If various things were identical in nature through the presence of a universal, they would not really be diverse; if a concrete thing were both universal and particular in nature, how would it be unified (*Pramāṇavārttika*, 'Pratyakṣa' 41; 'Svārthānumāna' 176-9)? Less polemically, Dharmakīrti points out that the fact that various things give rise to the same idea does not require the postulation of something that they all have in common; for we observe that a variety of herbs that have nothing in common have the same effect of alleviating fever (*Pramāṇavārttika*, 'Svārthānumāna' 73-4).

In reality, however, various individuals never give rise to the same *positive* idea, but only to a conception that is completely negative in content. That is to say, a particular cow may be seen as being different from all goats, all horses, all pots, all vegetables, and so on; another particular cow may be seen as being different from the same things. In so far as both cows are conceived of as being different from the same things, they are thought of as being of the same type; in themselves, however, they are quite distinct. This is the notorious *apohavāda*, 'the doctrine of exclusion', which asserts that general terms refer only to mentally constructed exclusion classes, *apohas*. The main thrust of the theory is that there is nothing at all positive to being an entity of a certain kind. Only individuals, which are inconceivable in nature, yet grasped immediately in perception (which is by definition devoid of all conceptualization), are real. The *apoha* doctrine was used by the Buddhists to question the reality of a wide range of phenomena that appear to be conceptually based, including substances, words and meanings (see Nominalism, Buddhist doctrine of).

The *apohavāda* evoked a spirited response on the part of realist thinkers, with numerous texts being devoted to the debate. The most serious objection to it, originally developed by Kumārila, is that it is unclear whether one can even recognize that a particular thing is *different* from other things without seeing positively that it and other things are of certain types. And if in attempting to identify a certain thing one's recognition of the 'other things' from which it differs were based on *apoha*, then one would have to be able to see that they exclude, among other things, the thing one is trying to identify, in which case one would already have to be able to identify something as being of a certain type in order to see that it is of a certain type (*Ślokavārttika*, 'Apohavāda' 2-, 65-6). Moreover, the *apohavāda* renders all words nearly synonymous: the only difference in meaning between the words 'cow' and

'horse' is that the former excludes horses while the latter excludes cows; otherwise, the vast number of the things each word excludes is identical (*ibid*. 53-4). In general, the realist arguments against the *apohavāda* raise an issue with which even modern nominalists must reckon, namely, while it may be possible to construct theories that make no reference to abstract entities, can one really understand the locutions of such theories without tacitly appealing to them?

The heated debate over universals was no mere intellectual exercise for Indian philosophers. The defenders of the reality of universals were concerned to preserve, at least up to a point, the validity of the distinctions of natural kinds upon which the prescriptions of scripture are based. The opponents of universals, on the other hand, sought ultimately to deny the reality of the world of ordinary experience and encourage the cultivation of a mystical awareness of an ineffable Absolute.

Use/mention distinction and quotation

Speakers 'use' the expressions they utter and 'mention' the individuals they talk about. Connected with the roles of used expressions and mentioned individuals is a way of uniting them and a characteristic mistake involving them. Usually the expression used in an utterance will not be the same as the individual mentioned, but the two can be made to converge. The means is quotation. Quotation is a special usage in which an expression is used to mention itself. A failure to distinguish between the roles of used expressions and mentioned individuals can lead to mistakes. Such mistakes are called use/mention confusions. In themselves use/mention confusions are a minor linguistic faux pas, *but under unfavourable conditions, they have the potential to cause greater problems.*

1 Use and mention

Though philosophers since Plato have distinguished between language and the world it is used to describe, the terms 'use' and 'mention' were first applied to these categories by the philosopher and logician Willard Quine in 1940. Quine's choice of the terms was intended to encourage associations with their ordinary meanings. To *use* an expression linguistically is to use it as a tool; to employ it towards a linguistic end. The ends are performances of speech acts, such as making claims, asking questions and giving responses. In contrast, to *mention* an individual is to say something about it; to make it the topic of conversation between speaker and listener. An individual mentioned in a speech act is one whose characteristics help determine how the act is to be evaluated: whether a claim is true, a question pertinent or a response correct depends on the individuals mentioned in the act and what is said about them.

In every communicative setting, some expression is used and, in most, some individual is mentioned. For example, a speaker uttering (1) below succeeds in making a claim about Tucson, the capital city of the state of Arizona:

(1) Tucson is dry.

By using the words 'Tucson', 'is' and 'dry' in the appropriate order, the city is mentioned. To say that Tucson is mentioned is to say that it is Tucson's weather, rather than that of Rangoon or Vienna, which is relevant to the truth of the claim. Greetings, such as 'Good Morning' or 'Hello', are examples of speech acts in which no individual is mentioned; their success depends only on the circumstances and the speaker's intentions.

While thinking about the categories of expressions used and individuals mentioned, one should bear in mind that the distinction divides the roles individuals can play rather than the kinds of individuals that can play these roles. That the distinction does not separate individuals by kinds is shown by the fact that linguistic expressions can play both parts: expressions can be mentioned as well as used. By uttering (2), for example, a speaker manages to mention the name 'Tucson' and, in fact, to say something true about it:

(2) The name of the capital city of Arizona contains six letters.

(1) should be compared with (2). The former uses the name of the city to mention the city, while the latter uses a description of the name to mention the name itself.

A detailed understanding of use and mention requires that one draw a distinction between the 'type' of an expression and 'tokens' of that type (see Type/token distinction). Expression tokens are concrete objects, individual marks or sounds made of raw materials: ink, perhaps; or sound waves. Types are abstract individuals and, as such, not made of anything. There is only one word 'Tucson' in the English language (so 'Tucson' is a type), of which there are several tokens in this entry.

The type/token distinction brings with it possibilities for what is used and mentioned. Both tokens and types can be used. To use a token, one has to utter it with the intention of saying something. Using a type requires the same intention, but also requires that the token have the right shape or sound. Tokens and types can also be mentioned. (2) mentions the type and (3) the token used in (1):

(3) The first word token in the first example sentence of the entry on 'Use/mention distinction and quotation' in the *Routledge Encyclopedia of Philosophy* has six letters.

2 Standard uses of quotation and quasi-quotation

Expressions of each grammatical category have what may be called standard uses. The standard use of noun phrases is to mention: 'Tucson', 'The name of the capital city of Arizona' and 'The first word token…*Philosophy*' from (3) above are all used in standard fashion. Expressions of most other categories have standard uses which do not involve mentioning. Articles and quantifiers ('every', 'some', 'all', 'most') do not themselves mention, but rather help determine the range of individuals that are mentioned. Conjunctions govern the manner in which the meanings of compound expressions depend on the meanings of their constituents. According to some theories, adjectives, adverbs and verbs mention relations, properties or events. According to other theories, they do not mention at all.

Along with their standard uses, expressions also have nonstandard uses. Chief among these is their use in quotation. Quotation is a way of using an expression to mention itself. It is the most general and efficient way of talking about expressions. Instead of the long-winded description in (2), a speaker wanting to mention 'Tucson' can simply quote it:

(4) 'Tucson' has six letters.

From the notational point of view, quotation is trivial. Its basic rule is simple: to quote an expression, enclose a token of it in quotation marks - the purpose of the marks being to indicate the nature of the usage. Or it can be simpler yet; one can leave out the marks when it is clear from the context that one wants to talk about an expression rather than use it in the standard way. (Passages which are indented or examples marked by numbers - as in this entry - are quoted using this method.) Quotation is generally used to mention expression types, unless there is an explicit qualification to the contrary.

Quotation is a leveller. No matter what they may standardly be used to mention, when quoted, all nouns mention expressions. It is instructive to compare (1) and (4) on this count to see how quotation can bring about a change in subject matter: (1) is about a large city, while (4), which differs only in the addition of a set of quotation marks, is about a medium-sized word. The effect of quotation on other categories of expressions is even more significant. It reduces the whole variety of standard uses to one. No matter what their standard use may be, when quoted, expressions of all categories become mentioning expressions. This effect can be seen in the example below:

(5) 'A' is an article and 'and' is a conjunction.

In this sentence, the first token of the word 'a' and the second token of the word 'and' are used to mention, while the second token of the word 'a', the first of 'and' and the only one of 'an' operate in standard fashion.

Related to regular quotation is a notation invented by Quine (1940), called 'quasi-quotation'. Quine, who has done more to encourage the correct use of quotation marks than any other writer, created quasi-quotation to help in capturing linguistic generalizations. Quasi-quotation treats an expression in two ways. Towards one part of the expression ('Čamp;' in the example below) it behaves as regular quotation. The other part or parts (' α' and ' β' in the example below) it treats as indeterminate elements that can mention any expression within a specific category. The marks of quasi-quotation are called corner quotes (' $\ulcorner$ ' on the left and ' $\urcorner$ ' on the right). A full quasi-quotation consisting of the expression enclosed by two corners is itself an indeterminate that can mention any expression consisting of the quoted part and any expression mentioned by the indeterminate part. To take an example from logic, let ' α' and ' β' be indeterminates mentioning sentences and 'Čamp;' be the conjunction symbol. A rule giving the extensional semantics for conjunction can be stated using quasi-quotation:

(6) $\ulcorner\alpha \,\&\, \beta\urcorner$ is true iff α is true and β is true,

where ' $\ulcorner\alpha \,\&\, \beta\urcorner$ ' mentions an expression that is a conjunction of the sentences mentioned by ' α' and ' β'. If α is 'Cicero died' and β is 'Caesar spoke', then $\ulcorner\alpha \,\&\, \beta\urcorner$ is the result of writing α followed by 'Čamp;' followed by β, namely 'Cicero died and Caesar spoke'.

3 Use/mention confusions

The distinction between use and mention can turn slippery. When it does and one loses hold of it, use/mention

confusions can occur. The typical result of such a confusion is that a speaker ends up making a claim about nonlinguistic individuals that is appropriate only to expressions or making a claim about expressions that is only appropriate to nonlinguistic individuals. Where the distinction between use and mention turns most slippery is on the subject of abstract individuals. Numbers and expressions used to mention them can be especially hard to keep apart. The category of numbers includes whole numbers such as 1 and 3, ratios such as $\frac{1}{2}$ and $\frac{4}{3}$ and irrational numbers such as π. The expressions that mention them include the numerals '1' and '3', the fractions '$\frac{1}{2}$' and '$\frac{4}{3}$' and the Greek letter 'π'. Classroom presentations of ratios and fractions commonly involve use/mention confusions. Students are often told something like the following:

Fractions consist of one number divided by another. The number to be divided, called the 'numerator', is placed on the top, while the number to divide by, called the 'denominator', is placed on the bottom, with a line between the two. So, 2 is the numerator and 3 the denominator of $\frac{2}{3}$.

However, the clever student may wonder how this could be. Since $\frac{2}{3}$ is the same quotient as $\frac{4}{6}$, the above remarks suggest that they ought to be the same fraction. Therefore 3 ought to be the denominator of both (on the grounds that the denominators of identicals are identical), but it is not. This puzzle exposes the use/mention confusion. The teacher has confused fractions with ratios. '$\frac{2}{3}$' is a fraction; $\frac{2}{3}$ a ratio. Only fractions have numerators and denominators, while it is the ratios mentioned by fractions that may be identical. The numeral '3' is the denominator of the fraction '$\frac{2}{3}$', but it is the *ratios* $\frac{2}{3}$ and $\frac{4}{6}$ which are identical. Because '$\frac{2}{3}$' is not the same fraction as '$\frac{4}{6}$', they need not, and indeed do not, have the same denominator.

The need to achieve clarity and avoid confusions such as the one above is the main reason why it is important to maintain a clear separation between use and mention. As far as errors go, the mix-up with fractions and ratios is probably mid-level. Some use/mention confusions are of less consequence. Others pose greater problems (see Modal operators §1). Where subtlety and precision are at a premium, as they are in logic and linguistics, use/mention confusions can severely impair the intelligibility of a discussion.

Utilitarianism

Utilitarianism is a theory about rightness, according to which the only good thing is welfare (wellbeing or 'utility'). Welfare should, in some way, be maximized, and agents are to be neutral between their own welfare, and that of other people and of other sentient beings.

The roots of utilitarianism lie in ancient thought. Traditionally, welfare has been seen as the greatest balance of pleasure over pain, a view discussed in Plato. The notion of impartiality also has its roots in Plato, as well as in Stoicism and Christianity. In the modern period, utilitarianism grew out of the Enlightenment, its two major proponents being Jeremy Bentham and John Stuart Mill.

Hedonists, believing that pleasure is the good, have long been criticized for sensualism, a charge Mill attempted to answer with a distinction between higher and lower pleasures. He contended that welfare consists in the experiencing of pleasurable mental states, suggesting, in contrast to Bentham, that the quality, not simply the amount, of a pleasure is what matters. Others have doubted this conception, and developed desire accounts, according to which welfare lies in the satisfaction of desire. Ideal theorists suggest that certain things are just good or bad for people, independently of pleasure and desire.

Utilitarianism has usually focused on actions. The most common form is act-utilitarianism, according to which what makes an action right is its maximizing total or average utility. Some, however, have argued that constantly attempting to put utilitarianism into practice could be self-defeating, in that utility would not be maximized by so doing. Many utilitarians have therefore advocated non-utilitarian decision procedures, often based on common sense morality. Some have felt the appeal of common sense moral principles in themselves, and sought to reconcile utilitarianism with them. According to rule-utilitarianism, the right action is that which is consistent with those rules which would maximize utility if all accepted them.

There have been many arguments for utilitarianism, the most common being an appeal to reflective belief or 'intuition'. One of the most interesting is Henry Sidgwick's argument, which is ultimately intuitionist, and results from sustained reflection on common sense morality. The most famous argument is Mill's 'proof'. In recent times, R.M. Hare has offered a logical argument for utilitarianism.

The main problems for utilitarianism emerge out of its conflict with common sense morality, in particular justice, and its impartial conception of practical reasoning.

1 Introduction and history

Defining utilitarianism is difficult, partly because of its many variations and complexities, but also because the utilitarian tradition has always seen itself as a broad church. But before offering a history, we must supply a working definition. First, utilitarianism is, usually, a version of *welfarism*, the view that the only good is welfare (see Welfare). Second, it assumes that we can compare welfare across different people's lives (see Economics and ethics). Third, it is a version of consequentialism (see Consequentialism). Consequentialists advocate the impartial maximization of certain values, which might include, say, equality. Utilitarianism is welfarist consequentialism, in its classical form, for instance, requiring that any action produce the greatest happiness (see Happiness).

The concern with welfare, its measurement and its maximization is found early, in Plato's *Protagoras*. In the process of attempting to prove that all virtues are one, Socrates advocates *hedonism*, the welfarist view that only pleasurable states of mind are valuable, and that they are valuable solely because of their pleasurableness (see Plato §9; Socrates §24; Hedonism).

The debate in the *Protagoras* is just one example of the many discussions of welfare in ancient ethics (see Eudaimonia). Some have seen Greek ethics as primarily egoistic, addressing the question of what each individual should do to further their own welfare (see Egoism and altruism §4). Utilitarianism, however, is impartial.

The Stoics, who followed Plato and Aristotle, began to develop a notion of impartiality according to which self-concern extended rationally to others, and eventually to the whole world (see Stoicism §18). This doctrine, allied to Christian conceptions of self-sacrifice, and conceptions of rationality with roots in Plato which emphasize the objective supra-individual point of view, could plausibly be said to be the source of utilitarian impartiality (see

Impartiality).

In the modern period, the history of utilitarianism takes up again during the Enlightenment. The idea of impartial maximization is found in the work of the eighteenth-century Scottish philosopher Francis Hutcheson (1755) (see Hutcheson, F. §2). The work of his contemporary, David Hume (1751), also stressed the importance to ethics of the notion of 'utility' (see Hume, D. §4.1). A little later, the so-called 'theological utilitarians', Joseph Priestley (1768) and William Paley (1785), argued that God requires us to promote the greatest happiness (see Priestley, J.; Paley, W.). Meanwhile, in France, Claude Helvétius (1758) advocated utilitarianism as a political theory, according to which the task of governments is to produce happiness for the people. He influenced one of the most extreme of all utilitarians, William Godwin (1793) (see Helvétius, C.; Godwin, W.).

It was Jeremy Bentham, however, who did most to systematize utilitarianism. Bentham's disciple, J.S. Mill, was the next great utilitarian, and he was followed by Henry Sidgwick. G.E. Moore (1903) distanced himself from Mill's hedonism, and offered an influential 'ideal' account of the good. One of the most important recent versions of utilitarianism is that of R.M. Hare (see Moore, G.E.; Hare, R.M.).

2 Conceptions of utility

Before you can maximize utility, you need to know what utility is. It is essential to note that the plausibility of utilitarianism as a theory of right action does not depend on any particular conception of welfare. An account of the good for a person is different from an account of right action (see Right and good).

Utilitarians have held many different views of utility. The 'classical' utilitarians - primarily Bentham (1789) and Mill (1861) - were hedonists. There are many objections to hedonism. What about masochists, for example, who seem to find pain desirable? Well, perhaps pain can be pleasurable. But is there really something common - pleasure - to all the experiences that go to make up a happy life? And would it be rational to plug oneself into a machine that gave one vast numbers of pleasurable sensations? Here there may be a move towards the more eclectic view of Sidgwick (1874), that utility consists in desirable consciousness of any kind. Some philosophers, however, such as Nietzsche (1888), have suggested that a life of mere enjoyment is inauthentic.

Hedonists have been criticized for sensualism for millennia J.S. Mill sought to answer the charge, suggesting that hedonists do not have to accept that all pleasurable experiences - drinking lemonade and reading Wordsworth - are on a par, to be valued only according to the *amount* of pleasure they contain. Bentham and others had suggested that the value of a pleasure depends mainly on its intensity and its duration, but Mill insisted that the *quality* of a pleasure - its nature - also influences its pleasurableness and hence its value. But why must the effect on value of the nature of an experience be filtered through pleasurableness? Why cannot its nature by itself add value?

Perhaps the most serious objection to any theory that welfare consists in mental states is the so-called 'experience machine'. This machine is better than the pleasure machine, and can give you the most desirable experiences you can imagine. Would it be best for you to be wired up to it throughout your life? Note that this is not the question whether it would be *right* to arrange for yourself to be wired up, leaving all your obligations in the real world unfulfilled. Even a utilitarian can argue that that would be immoral.

Some people think it makes sense to plug in, others that it would be a kind of death. If you are one of the latter, then you might consider moving to a desire theory of utility, according to which what makes life good for you is your desires' being maximally fulfilled. On the experience machine, many of your desires will remain unfulfilled. You want not just the experience of, say, bringing about world peace, but actually to bring it about. Desire theories have come to dominate contemporary thought because of economists' liking for the notion of 'revealed preferences' (see Rationality, practical). Pleasures and pains are hard to get at or measure, whereas people's preferences can be stated, and inferred objectively from their behaviour.

A simple desire theory fails immediately. I desire the glass of liquid, thinking it to be whisky. In fact it is poison, so satisfying my desire will not make me better off. What desire theorists should say here is that it is the satisfaction of intrinsic desires which counts for wellbeing. My intrinsic desire is for pleasure, the desire for the drink being merely derived.

The usual strategy adopted by desire theorists is to build constraints into the theory in response to such counterexamples: what makes me better off is not the fulfilment of my desires, but of my informed desires.

But why do desire theorists so respond to such counterexamples? It is probably because they already have a view of utility which guides them in the construction of their theories. This means that desire theories are themselves idle, which is to be expected once we realize that the fulfilment of a desire is in itself neither good nor bad for a person. What matters is whether what the person desires, and gets, is good or bad.

For reasons such as this, there is now a return to ancient *ideal* theories of utility, according to which certain things are good or bad for beings, independently in at least some cases of whether they are desired or whether they give rise to pleasurable experiences (see Perfectionism). Another interesting ancient view which has recently been revived is that certain nonhedonistic goods are valuable, but only when they are combined with pleasure or desire-fulfilment (see Plato, *Philebus* 21a-22b). The nonhedonistic goods suggested include knowledge and friendship. Questions to ask of the ideal theorist include the following. What will go on your list of goods? How do you decide? How are the various items to be balanced?

3 Types of utilitarianism

Theories of right and wrong have to be about something, that is, have to have a focus. Usually, at least in recent centuries, they have focused on actions, attempting to answer the questions, ‘Which actions are right?’, and, ‘What makes those actions right?’. The ancients also asked these questions, but were concerned also to focus on lives, characters, dispositions and virtues. Nearly all forms of utilitarianism have focused on actions, but in recent decades there has been some interest in utilitarianism as applied to motives, virtues and lives as a whole.

Utilitarianism is a form of consequentialism. But it is important to note that, since utilitarians can attach instrinsic moral importance to acts (especially, of course, the act of maximizing itself), there are problems in attempting to capture the nature of utilitarianism using the act/consequence distinction. A recent alternative has been to employ the ‘agent-neutral’/‘agent-relative’ distinction. Agent-neutral theories give every agent the same aim (for example, that utility be maximized), whereas agent-relative theories give agents different aims (say, that *your* children be looked after). Logically, however, there is nothing to prevent a utilitarian’s insisting that *your* aim should be that *you* maximize utility. Though this theory would be practically equivalent to an agent-neutral theory, its possibility suggests there may be problems with attempting to use the agent-neutral/agent-relative distinction to capture the essence of utilitarianism.

What clearly distinguishes utilitarianism from other moral theories is what it requires and why, so we should now turn to that. The commonest, and most straightforward, version of utilitarianism is *act-utilitarianism*, according to which the criterion of an action’s rightness is that it maximize utility.

Act-utilitarians might offer two accounts of rightness. The objectively right action would be that which actually does maximize utility, while the subjectively right action would be that which maximizes expected utility. Agents would usually be blamed for not doing what was subjectively right.

Another distinction is between *total* and *average* forms. According to the total view, the right act is the one that produces the largest overall total of utility. The average view says that the right action is that which maximizes the average level of utility in a population. The theories are inconsistent only in cases in which the size of a population is under consideration. The most common such case occurs when one is thinking of having a child. Here, the average view has the absurd conclusion that I should not have a child, even if its life will be wonderful and there will be no detrimental effects from its existence, if its welfare will be lower than the existing average.

But the total view also runs into problems, most famously with Derek Parfit’s ‘repugnant conclusion’ (1984), which commits the total view to the notion that if a population of people with lives barely worth living is large enough it is preferable to a smaller population with very good lives. One way out of this problem is to adopt a *person-affecting* version of utilitarianism, which restricts itself in scope to existing people. But there are problems with this view (see Parfit 1984: ch. 18). Recently, certain writers have suggested that one way to avoid the ‘repugnant conclusion’ would be to argue that there are *discontinuities* in value, such that once welfare drops below a certain level the loss cannot be compensated for by quantity. There is a link here with Mill’s view of the relation of higher pleasures to lower.

Imagine being an act-utilitarian, brought up in an entirely act-utilitarian society. You will have to spend much time calculating the utility values of the various actions open to you. You are quite likely to make mistakes, and, being

human, to cook the books in your own favour.

For these reasons, most act-utilitarians have argued that we should not attempt to put act-utilitarianism into practice wholesale, but stick by a lot of common sense morality (see Common-sense ethics). It will save a lot of valuable time, is based on long experience, and will keep us on the straight and narrow. Act-utilitarians who recommend sole and constant application of their theory as well as those who recommend that we never consult the theory and use common sense morality can both be called *single-level* theorists, since moral thinking will be carried on only at one level. Most utilitarians have adopted a *two-level* theory, according to which we consult utilitarianism only sometimes - in particular when the principles of ordinary morality conflict with one another.

The main problem with two-level views is their psychology. If I really accept utilitarianism, how can I abide by a common sense morality I know to be a fiction? And if I really do take that common sense morality seriously, how can I just forget it when I am supposed to think as a utilitarian? The two-level response here must be that this is indeed a messy compromise, but one made to deal with a messy reality.

Act-utilitarianism is an extremely demanding theory, since it requires you to be entirely impartial between your own interests, the interests of those you love, and the interests of all. The usual example offered is famine relief. By giving up all your time, money and energy to famine relief, you will save many lives and prevent much suffering. Utilitarians often claim at this point that there are limits to human capabilities, and utilitarianism requires us only to do what we can. But the sense of ‘can’ here is quite obscure, since in any ordinary sense I can give up my job and spend my life campaigning for Oxfam.

The demandingness objection seems particularly serious when taken in the context of widespread non-compliance with the demands of act-utilitarian morality. Most people do little or nothing for the developing world, and this is why the moral demands on me are so great. An argument such as this has been used to advocate *rule-utilitarianism*, according to which the right action is that which is in accord with that set of rules which, if generally or universally accepted, would maximize utility. (The version of the theory which speaks of the rules that are *obeyed* is likely to collapse into act-utilitarianism; see Lyons 1965.)

Unlike act-utilitarianism, which is a *direct* theory in that the rightness and wrongness of acts depends directly on whether they fit with the maximizing principle, rule-utilitarianism is an *indirect* theory, since rightness and wrongness depend on rules, the justification for which itself rests on the utilitarian principle.

The demandingness of act-utilitarianism has not been the main reason for adopting rule-utilitarianism. Rather, the latter theory has been thought to provide support for common sense moral principles, such as those speaking against killing or lying, which appear plausible in their own right.

Rule-utilitarianism has not received as much attention as act-utilitarianism, partly because it detaches itself from the attractiveness of maximization. According to rule-utilitarianism there may be times when the right action is to bring about less than the best possible world (such as when others are not complying). But if maximization is reasonable at the level of rules, why does it not apply straightforwardly to acts?

4 Arguments for utilitarianism

The most famous argument for utilitarianism is John Stuart Mill’s ‘proof’ (1861). This has three stages:

1 Happiness is desirable.
2 The general happiness is desirable.
3 Nothing other than happiness is desirable.

Each stage has been subjected to much criticism, especially the first. Mill was an empiricist, who believed that matters of fact could be decided by appeal to the senses (see Empiricism). In his proof, he attempted to ground evaluative claims on an analogous appeal to desires, making unfortunate rhetorical use of ‘visible’ and ‘desirable’. The first stage suggests to the reader that if they consult their own desires, they will see that they find happiness desirable.

The second stage is little more than assertion, since Mill did not see the vastness of the difference between egoistic and universalistic hedonism (utilitarianism). In an important footnote (1861: ch. 5, para. 36), we see the

assumption that lies behind the proof: the more happiness one can promote by a certain action, the stronger the reason to perform it. Egoists will deny this, but it does put the ball back in their court.

The final stage again rests on introspection, the claim being that we desire, ultimately, only pleasurable states. Thus even a desire for virtue can be seen as a desire for happiness, since what we desire is the pleasure of acting virtuously or contemplating our virtue. One suspects that introspection by Mill's opponents would have had different results.

Perhaps the most common form of utilitarianism, as of any other moral theory, is, in a weak sense, intuitionist (see Intuitionism in ethics). To many, utilitarianism has just seemed, taken by itself, reasonable - so reasonable, indeed, that any attempt to prove it would probably rest on premises less secure than the conclusion. This view was expressed most powerfully by Henry Sidgwick (1874). Sidgwick supported his argument with a painstaking analysis of common sense morality. Sidgwick also believed that egoism was supported by intuition, so that practical reason was ultimately divided (see Egoism and altruism §§1, 3).

In the twentieth century, R.M. Hare wished to avoid appeal to moral intuition, which he saw as irrational. According to Hare (1981), if we are going to answer a moral question such as, 'What ought I to do?', we should first understand the logic of the words we are using. In the case of 'ought', we shall find that it has two properties: prescriptivity (it is action-guiding) and universalizability (I should be ready to assent to any moral judgment I make when it is applied to situations similar to the present one in their universal properties) (see Prescriptivism). Hare argues that putting yourself in another's position properly - 'universalizing' - involves taking on board their preferences. Once this has been done, the only rational strategy is to maximize overall preference-satisfaction, which is equivalent to utilitarianism.

Hare's moral theory is one of the most sophisticated since Kant's, and he does indeed claim to incorporate elements of Kantianism into his theory (see Kantian ethics). Objectors have claimed, however, that, rather like Kant himself, Hare introduces 'intuitions' (that is, beliefs about morality or rationality) through the back door. For example, the logic of the word 'ought' may be said not to involve a commitment to the rationality of maximization even in one's own case.

5 Problems for utilitarianism

There are many technical problems with the various forms of utilitarianism. How are pleasure and pain to be measured? Which desires are to count? Is knowledge a good in itself? Should we take into account actual or probable effects on happiness? How do we characterize the possible world which is to guide us in our selection of rules? These are problems for the theorists themselves, and there has been a great deal said in attempts to resolve them.

More foundational, however, is a set of problems for any kind of utilitarian theory, emerging out of utilitarianism's peculiarly strict conception of impartiality. A famous utilitarian tag, from Bentham, is, 'Everybody to count for one, nobody for more than one'. This, however, as Mill implies (1861: ch. 5, para. 36), is slightly misleading. In a sense, according to utilitarianism, no one matters; all that matters is the level of utility. What are counted equally are not persons but pleasures or utilities.

This conception of impartiality has made it easy for opponents of utilitarianism to dream up examples in which utilitarianism seems to require something appalling. A famous such example requires a utilitarian sheriff to hang an innocent man, so as to prevent a riot and bring about the greatest overall happiness possible in the circumstances (see Crime and punishment §2).

Utilitarians can here respond that, in practice, they believe that people should abide by common sense morality, that people should accept practical principles of rights for utilitarian reasons (see §2). But this misses the serious point in many of these objections: that it matters not just how much utility there is, but how it is shared around. Imagine, for example, a case in which you can give a bundle of resources either to someone who is well-off and rich through no fault of their own, or to someone who is poor through no fault of their own. If the utility of giving the bundle to the rich person is only slightly higher than that of giving it to the poor person, utilitarianism dictates giving it to the rich person. But many (including some consequentialists) would argue that it is reasonable to give some priority to the worse-off.

These are problems at the level of the social distribution of utility. But difficulties arise also because of the fact that human agents each have their own lives to live, and engage in their practical reasoning from their own personal point of view rather than from the imaginary point of view of an 'impartial spectator'. These problems have been stated influentially in recent years by Bernard Williams (Smart and Williams 1973), who puts them under the heading of what he calls 'integrity' (see Williams, B.A.O. §4).

In a famous example, Williams asks us to imagine the case of Jim, who is travelling in a South American jungle. He comes across a military firing squad, about to shoot twenty Indians from a nearby village where some insurrection has occurred. The captain in charge offers Jim a guest's privilege. Either Jim can choose to shoot one of the Indians himself, and the others will go free, or all twenty will be shot by the firing squad.

Williams' point here is not that utilitarianism gives the wrong answer; indeed he himself thinks that Jim should shoot. Rather, it is that utilitarianism reaches its answer too quickly, and cannot account for many of the thoughts we know that we should have ourselves in Jim's situation, such as, 'It is I who will be the killer'. Practical reasoning is not concerned only with arranging things so that the greatest utility is produced. Rather it matters to each agent what role they will be playing in the situation, and where the goods and bads occur. This point emerges even more starkly if we imagine a variation on the story about Jim, in which the captain asks Jim to commit suicide so as to set an example of courage and nobility to the local populace, on the condition that if he does so the twenty Indians will go free. The utility calculations are as clear, perhaps clearer, than in the original story. But it is only reasonable that Jim in this story should think it relevant that it is he who is going to die. To any individual, it matters not only how much happiness there is in the world, but who gets it.

Utopianism

Utopianism is the general label for a number of different ways of dreaming or thinking about, describing or attempting to create a better society. Utopianism is derived from the word utopia, coined by Thomas More. In his book Utopia *(1516) More described a society significantly better than England as it existed at the time, and the word* utopia *(good place) has come to mean a description of a fictional place, usually a society, that is better than the society in which the author lives and which functions as a criticism of the author's society. In some cases it is intended as a direction to be followed in social reform, or even, in a few instances, as a possible goal to be achieved.*

The concept of utopianism clearly reflects its origins. In Utopia *More presented a fictional debate over the nature of his creation. Was it fictional or real? Was the obvious satire aimed primarily at contemporary England or was it also aimed at the society described in the book? More important for later developments, was it naïvely unrealistic or did it present a social vision that, whether achievable or not, could serve as a goal to be aimed at? Most of what we now call utopianism derives from the last question. In the nineteenth century Robert Owen in England and Charles Fourier, Henri Saint-Simon and Étienne Cabet in France, collectively known as the utopian socialists, popularized the possibility of creating a better future through the establishment of small, experimental communities. Karl Marx, Friedrich Engels and others argued that such an approach was incapable of solving the problems of industrial society and the label 'utopian' came to mean unrealistic and naïve. Later theorists, both opposed to and supportive of utopianism, debated the desirability of depicting a better society as a way of achieving significant social change. In particular, Christian religious thinkers have been deeply divided over utopianism. Is the act of envisaging a better life on earth heretical, or is it a normal part of Christian thinking?*

Since the collapse of communism in eastern Europe and the former Soviet Union, a number of theorists have argued that utopianism has come to an end. It has not; utopias are still being written and intentional communities founded, hoping that a better life is possible.

1 Background

Utopianism has existed at least as long as written history. Descriptions of better societies are found on a Sumerian clay tablet, in the Old Testament and among early Greek writers. There is considerable debate over whether or not it is a universal human phenomenon, but the only culture that seems to be lacking an early utopian tradition is Japan. The term that is used to characterize the phenomenon first occurs in the title of Thomas More's book *Libellus vere aureus nec minus salutaris quam festivus de optimo reip[ublicae] statu, deq[ue] noua Insula Vtopia* (1516), now known simply as *Utopia*. The word was based on the root *topos*, meaning *place*, and the prefix *u* or *ou*, meaning *no* or *not*. Thus, strictly speaking, utopia refers simply to a nonexistent place, but More punned on an alternative prefix, *eu* or *good*. As a result the word *utopia* came to refer to a nonexistent good place. Even though some scholars prefer to retain the distinction between *utopia* and *eutopia*, common usage conflates them (Sargent 1994).

The word *utopia* was rapidly added to most European languages and was in fairly common use by the end of the sixteenth century, being employed as part of a book title as early as 1520. The utopia as a literary genre developed quickly (Hölscher 1996); more than twenty utopias were published in the sixteenth century after More's*Utopia* (Sargent 1988), and the first study of this new phenomenon was published in 1704 (Ahlefeld 1704; see Widdicombe 1992 for a discussion of early studies).

Utopia is a small but complex book in that it presages much of the later debate over the importance of utopianism. Within *Utopia* More presented arguments for and against his invention, using arguments that have a long history and still continue to be used today.

Discussion of utopianism and its role in political philosophy surfaces as early as Aristotle, who in *Politics* criticized Plato and other projectors of better societies. Aristotle (§§27-8) argued that depicting an ideal society is the wrong approach to political theorizing. He suggested that both the criticism of contemporary societies and the development of proposals for bettering them need to be based on a detailed, realistic understanding of how human beings behave and the ways that political systems are both shaped by, and can shape, that behaviour. Plato can be

interpreted as doing just that, particularly in his *Laws*, which contrary to popular opinion is closer to later utopian thinking than his *Republic*. Aristotle's position, however, still forms one of the starting points for much contemporary criticism of utopianism. Today both Marxists and liberals use utopianism as a pejorative term, meaning 'unrealistic' or 'against human nature' or simply 'too idealistic'. Others have argued that utopianism is essential to any positive social change and may even be part of what makes us human (see Human nature §1).

In the late 1920s Karl Mannheim, primarily known as the theorist of the sociology of knowledge, used the concepts utopia and ideology as the two basic mental constructs that distort political discourse. Mannheim hoped to rid the words utopia and ideology of their negative meanings and reconstitute them as means of understanding the ways that certain social groups perceive the world around them. He first developed these ideas in his *Ideology and Utopia* (1929). In 1935, in an influential encyclopedia article, he defined the two concepts succinctly:

> The term utopian, as here used, may be applied to any process of thought which receives its impetus not from the direct source of reality but from concepts, such as symbols, fantasies, dreams, ideas and the like, which in the most comprehensive sense of that term are non-existent. Viewed from the standpoint of sociology, such mental constructs may in general assume two forms: They are ideological if they serve the purpose of glossing over or stabilizing the existing social reality; utopian if they inspire collective activity which aims to change such reality to conform with their goals, which transcend reality.
>
> (Mannheim 1935)

Mannheim's definitions influenced the use of the words, although not in the way he intended. His definition reinforced the old message that to be utopian meant to be naïve and out of touch with the real world. Mannheim scholars now consider *Ideology and Utopia* to be a minor part of his work, but his definitions are still used, not always accurately, by scholars of both ideology and utopianism (see Ideology §1).

2 Utopian socialism

Historically the most important critics of utopianism after Aristotle were Karl Marx and Friedrich Engels. In his *Die Entwicklung des Sozialismus von der Utopie zur Wissenschaft (Socialism: Utopian and Scientific)*, published in 1882, Engels coined the phrase 'utopian socialist' to describe Owen, Fourier, Saint-Simon and, in some editions, Cabet, whose idealistic proposals he regarded as distinctly inferior to Marx's 'scientific socialism'. Among these writers only Cabet wrote a work that a narrow definition would call a utopia - *Voyage en Icarie* (1840). Owen and Fourier described social systems based on relatively small communities, now generally called 'intentional communities' but in the past frequently called 'utopian communities'. Owen and Cabet actually participated in the development of such communities - Owen in the UK and the USA and Cabet in the USA - while followers of Fourier and Saint-Simon built them, mostly in France and the USA. Such communities are now generally thought of as examples of utopianism, and there are currently thousands of them based in at least twenty-one countries, the best-known example being the kibbutz movement in Israel.

Engels' primary target was not the building of small communities; in fact at one time he actually praised such community construction, using the example of the Rappites in Pennsylvania. What bothered the Marxists was that the utopian socialists made what Marx and his followers thought were unwarranted assumptions about human nature and about their own ability to predict and construct a better future. For all of his desire to overthrow the currently existing socio-economic system, Marx was adamant that a future constructed by people freed from domination could not be predicted. Marxists also argued that the utopian socialists were extremely naïve about the problems of constructing such a future society and the opposition that would be brought against any attempt to do so. Marxists contended that the construction of small communities was the wrong approach because they would never be allowed to succeed or, if they were, it would be because they were no threat to those in power. None of the communities built by the utopian socialists lasted very long (the seven Icarian communities founded by the followers of Cabet had a combined life span of fifty years), and none ever posed a threat. In contrast, nearing the end of the twentieth century, certain religious intentional communities have been in existence for nearly two hundred years, while fifty years is no longer uncommon and twenty-five years is almost the norm, even for secular communities; however, as before, these are not in any real sense threats to the existing order in any of the countries in which they exist (see Communism).

3 Utopian social theory

While the main line of criticism of utopianism initially developed in the context of utopian socialism and the small community, it was not that aspect of utopianism that became the focus for either its attackers or defenders, and Marxists have appeared in both ranks. Both Marxists and anti-Marxists argue that utopian thinking is naïve and unrealistic and makes assumptions about 'human nature' that will not withstand scrutiny. Marxists argue that 'human nature' is socially constructed and varies from society to society and time to time. Conservative, mostly Christian, opponents argue that sinful human nature is incapable of the improvements that they believe utopianism requires (Molnar 1967). It is true that many utopians have assumed that human nature is fundamentally 'good', usually meaning cooperative, but that contemporary society distorts that goodness; a new, better society would allow it to be expressed. However, such thinking is by no means the norm among utopians.

The modern debate around utopianism developed historically from its rejection. At the turn of the century, Edward Bellamy's novel, *Looking Backward 2000-1887* (1888), depicting a centralized socialist (he called it nationalist) utopia became the best-selling novel published up to that time and remained so until well into the twentieth century. Nationalist societies were founded in countries around the world. Bellamy effectively rekindled interest in utopianism after Engels had destroyed it. Since then, although deeply disputed, utopianism has never been ignored, even though for one fairly lengthy period it was the anti-utopians that kept it visible.

The anti-utopians generally regard utopias as blueprints of a desired perfect future society that must be achieved in all of its details. Since perfection is beyond human capabilities, the utopians, it is believed, will have to resort to force and violence to achieve utopia. Therefore, utopias are a first step that almost inevitably leads to totalitarianism (see Totalitarianism). Karl Popper is the best-known exponent of this position. In *The Open Society and Its Enemies*, he wrote: 'the Utopian approach can be saved only by the Platonic belief in one absolute and unchanging ideal, together with two further assumptions, namely (a) that there are rational methods to determine once and for all what this ideal is, and (b) what the best means of its realization are' ([1945] 1957, vol. 1: 161).

Utopians deny that utopias are the problem; the problem is with the believers. They argue that utopias are not blueprints of some future perfect society but act both as a critique of contemporary society and as a generalized goal rather than something to be realized in all its details. Utopias are seen by their defenders as expressions of the highest human aspirations.

This position is put most forcefully by the Dutch sociologist F.L. Polak in his *The Image of the Future*. He argued that our images of the future (whether utopias or dystopias) affect the actual future: 'We will view human society and culture as being magnetically *pulled* towards a future fulfilment of their own preceding and prevailing, idealistic images of the future, as well as being *pushed* from behind by their own realistic past' (1961, vol. 1: 15; original emphasis). Polak goes on to contend that 'if Western man now stops thinking and dreaming the materials of new images of the future and attempts to shut himself up in the present, out of longing for security and for fear of the future, his civilization will come to an end. He has no choice but to dream or to die, condemning the whole of Western society to die with him' (vol. 1: 53).

Ernst Bloch (§3) has become the most influential utopian thinker of the twentieth century. Bloch has become important for utopians because he argues that there always exists unrealized potential for positive social change. In other words, there are always utopian possibilities in any given situation. For scholars of utopianism, Bloch is significant today because in his most important work, *Das Prinzip Hoffnung* (*The Principle of Hope*, 1959), he demonstrates the long history of utopianism and its important contribution to social improvement.

For Bloch utopia is constantly on the horizon, not yet achieved, but open to the possibility of being achieved. It is these utopian aspirations and the hope that they can be realized that make human life bearable and a better life possible. For Bloch, human beings are active participants in creating that better future; we must think and act experimentally, driven by the utopian visions that Bloch found in art, literature, music, and social theory. In this he separates himself from the more deterministic versions of Marxism while at the same time seeing Marx as one of the great utopians of the past.

Utopianism has been a particular problem for Christian theorists, with some seeing any expression of utopianism as heretical (Molnar 1967) and others seeing it as an essential aspect of Christianity (Tillich 1971).

4 The end of utopia

Recent discussion of utopianism has focused on the so-called 'end of utopia'. Proponents of this have tended to identify utopian aspirations with the communist regimes of the former Soviet Union and eastern Europe. Thus, they saw in the collapse of communism a vindication of the futility of utopianism in the face of the obdurate material of human nature. The end of utopia was predicated on the same mis-identification of utopia with totalitarianism found earlier in Popper.

Just as with the 'end of ideology' debate of the 1950s - which was based on almost precisely the same arguments - utopia has not ended. In fact, it has been argued that the collapse of communism (a utopia that became a dystopia) was based on the development of a new and powerful utopia within communist countries, a utopia of freedom and materialism. Generalized, the position is that a new utopia is always needed to overcome the old dystopia. This point was made by the late Viktoriia Chalikova in *Utopiia rozhdaetsia iz utopii: cesse raznykh let (Utopia is Born by Utopia*, 1992).

Utopianism remains alive and well in all three of its forms. A constant stream of utopian novels is published in a wide variety of languages. The utopias found in these novels are more complex and self-reflective than in the earlier tradition, less certain that utopia can be both created and maintained, more aware both of the powerful forces marshalled against social betterment and the dangers inherent in the utopian enterprise, dangers pointed out by the anti-utopians. This has led one critic, Tom Moylan, to argue in his *Demand the Impossible* (1986) that a new type of utopia, the 'critical utopia', has been created. Moreover, since the beginning of the 1970s feminist novelists and theorists have produced a steady and continuing stream of feminist utopias.

There are more long-lived and well-established intentional communities currently in existence than at any time in the past, including the 1960s, when there was a great upsurge of community building. While generally little known, they are found throughout the world, with the greatest numbers in Australia, Europe and North America, and a number of ecologically based communities have recently been founded in the former Soviet Union. These communities express the desire of thousands of people to live a better life now.

Utopian theorists are also publishing more than ever before, arguing that social dreaming is both essential and potentially dangerous. Alongside Bloch and Polak, such theorists see the need to have utopian aspirations, but they are also intensely aware that there are always people ready to impose their utopia on others. None the less, the utopians argue, this does not in any way diminish the need to dream of a better life for all.

Vagueness

It seems obvious that there are vague ways of speaking and vague ways of thinking - saying that the weather is hot, for example. Common sense also has it that there is vagueness in the external world (although this is not the usual view in philosophy). Intuitively, clouds, for example, do not have sharp spatiotemporal boundaries. But the thesis that vagueness is real has spawned a number of deeply perplexing paradoxes and problems. There is no general agreement among philosophers about how to understand vagueness.

1 Vagueness in language and the world

Many linguistic terms are vague. But of what exactly does their vagueness consist? Consider, for example, the term 'bald'. This term has borderline cases of application. There are people to whom the term, as it is ordinarily used, neither clearly applies nor clearly fails to apply. In this respect, the term 'bald' is different from the term 'square root', say. There are no borderline square roots, nor could there be. Let us say that a general term (a word or phrase which potentially applies to many things) is intensionally vague (that is, vague with respect to its meaning) only if its meaning permits possible borderline cases of application. Then 'bald' is intensionally vague.

Vagueness can also be found in singular terms (words or phrases that potentially apply to single things). Consider, for example, 'the friend of Amy'. Suppose Amy has a love-hate relationship with Jane, without Amy clearly having any other friends. Then, it is indeterminate whether the singular term, 'the friend of Amy', designates Jane. So, 'the friend of Amy' has a possible borderline case of designation. And this indicates that it is intensionally vague.

It is plausible to suppose that intensional vagueness in general terms is more basic than intensional vagueness in singular terms, since uncontroversial examples of vague singular terms either contain vague general terms (non-relational or relational) or are the abstract singular counterparts to those terms. In the case of 'the friend of Amy', the term 'friend of' is intensionally vague.

The vagueness so far discussed does not require vagueness in the world. But worldly vagueness can be treated in a similar way. Suppose, as we normally do, that there really is a nonlinguistic property of being red, a property expressed by the predicate 'is red'. This predicate is vague and so is the property. Just as the former has borderline cases of application, so too the latter has borderline instances (objects which are neither clearly red nor clearly not red). Moreover, even if the actual world had not contained borderline red objects, still, intuitively, that would not have shown that the property, redness, is not vague. What the vagueness of properties seems to require is that there be possible borderline instances. Consider next concrete objects, for example, Mount Everest. Some molecules are definitely inside Everest and some are definitely outside. But intuitively, some have a borderline status: there is no determinate fact of the matter about whether they are inside or outside. Everest, then, has borderline spatiotemporal parts. In this way, it is like a cloud. So Everest is a vague concrete object.

There is another way in which, according to some philosophers, objects in the world can be vague. If, for a given object, o, there is an object, o', such that it is indefinite whether o is identical with o', then o, by virtue of its entering into an indefinite identity relation, is a vague object. Here is one possible example (due to D. Parfit, cited in Broome 1984). There is a club which has a clubhouse, a membership list and a set of rules. This club is never formally disbanded, but through time its members meet less and less frequently and the clubhouse becomes run down. There are no meetings for several years. Twelve years later, however, a few of the original members get together with some new people and start to meet once more in the same building (now redecorated). The club they belong to at this later date has the same name as the earlier one.

It has been held that the claim that the first club is identical with the second one is indefinite. Moreover, this indefiniteness, it has been suggested, is not an epistemic matter, since there is no further information which would settle the issue. On this view, each club has a vague identity and is thereby a vague object.

There is at least one respect in which the proposed characterizations of vagueness are incomplete. Consider the following sequence of conditionals, each of which includes the vague term 'tall':

(1a) If a man whose height is 7 feet is tall, then a man whose height is 6 feet 11 and $\frac{99}{100}$ inches is tall.

(1b) If a man whose height is 6 feet 11 and $\frac{99}{100}$ inches is tall, then a man whose height is 6 feet 11 and $\frac{98}{100}$ inches is tall.

⋮

(1*n*) If a man whose height is 5 feet and $\frac{1}{100}$ inches is tall, then a man whose height is 5 feet is tall.

Intuitively, there is no sharp dividing line between the true conditionals in this sequence and those that have some other value. This fact is not captured in the earlier account of intensional vagueness. But it seems to be part and parcel of our ordinary conception of the vagueness of terms such as 'tall' or 'bald'. Their vagueness is robust or resilient. And a corresponding point can be made about vague concrete objects. For example, it does not seem to be true that there is a sharp dividing line between the molecules that are inside Everest and those that have a borderline status.

2 Paradoxes and problems

The oldest puzzle of vagueness, which allegedly derives from Eubulides, is the paradox of the bald man. It goes as follows:

(2) A man with no hairs on his head is bald.
(3) For any number, *n*, if a man with *n* hairs on his head is bald then a man with $n+1$ hairs on his head is bald.
(4) Therefore, a man with ten thousand hairs on his head is bald.

The conclusion is derived from the premises via ten thousand applications of the classical logical rules of *modus ponens* and universal instantiation, so this argument is valid. Now, premise (2) is certainly true and the conclusion, (4), is certainly false, so it is inferred that premise (3) is false. Therefore, there is an *n* such that a man with *n* hairs on his head is bald and a man with $n+1$ is not. Therefore, the term 'bald' is precise, contrary to appearances. And what is true in this one case is true by parallel reasoning for any general term which is ordinarily classified as vague.

It is worth observing that the paradox of the bald man does not rely essentially on the use of a universal generalization. The same result can be generated by means of a sequence of (ten thousand) conditionals such as in (1a)-(1n), with (2) as a starting point. Since the conclusion, (4), is false, and (2) is true, then at least one of the conditionals must be false. So, given that (2) is true and that each conditional is either true or false, there must be an adjacent pair of conditionals such that the first is true and the second false. This runs directly counter to the idea that 'bald' is vague.

If the paradox of the bald man really does demonstrate that the term 'bald' is not vague, contrary to what we all ordinarily believe, then 'bald' cannot express a vague property. So, the property of being bald cannot itself be vague. Since the paradox of the bald man can be restated so as to apply to any vague general term, one overall conclusion which has been reached is that no general terms or properties are vague. This conclusion, of course, not only threatens the thesis that there are vague abstract objects but also challenges the idea that there is any such thing as vagueness in language at all, however it is understood.

There are also sorites arguments which attack the concrete objects of common sense, on the assumption that these objects have vague boundaries. These arguments, like the paradox of the bald man, can be stated without the use of a universal generalization.

There are other problems for the view that individual concrete objects are vague. One of these is directed against vague objects, conceived of as objects having indeterminate identities (Evans 1978). Suppose that '*a*' and '*b*' are (precise) singular terms for vague objects and that '$a = b$' is indefinite in truth-value. Then, if we let '∇' symbolize 'indefinitely', the following is true:

(5) $\nabla(a = b)$

(5) ascribes to *b* the property of being indefinitely identical with *a*. Now surely we have

(6) $\sim\nabla(a = a)$

and hence that *a* lacks the property of being indefinitely identical with a. By the principle that if object *o* and object *o′* differ in a property, then they are not identical (the contrapositive of Leibniz's Law; see Identity), it follows that *a* is not identical with *b*. Since, on the standard understanding of 'indefinitely', it cannot be the case both that it is indefinite whether *a* is identical with *b* and that *a* is not identical with *b*, there cannot be vague identities.

The deepest problems of vagueness, in my view, are the sorites paradoxes. And these arise whether or not there is vagueness in the nonlinguistic world.

3 Theories

It has been suggested that a proper understanding of vagueness requires the admission that truth and set membership come in degrees, rather than being 'all or nothing' (see Zadeh 1965, Goguen 1969). On this approach, real numbers in the interval from 0 to 1 are typically taken to be truth-values, with 1 being fully fledged truth and 0 being fully fledged falsity. The same numbers are assigned to the degrees to which objects belong to sets. So, for example, if Herbert is clearly bald, then the sentence

(7) Herbert is bald

is assigned the value 1, and Herbert is taken to belong to the set of bald men to degree 1. But if Herbert is a borderline case then (7) is assigned some number less than 1, say, 0.6, and the degree of Herbert's membership in the set of bald men is now taken to be 0.6 too. In general, a singular sentence '*Fa*' is treated as having the truth-value *n*, where $0 \leq n \leq 1$, if and only if the referent of '*a*' belongs to the set of *F*s to degree *n* (see Fuzzy logic).

A consequence of this approach is that vague predicates do not sharply divide the world into those things to which they apply and those things to which they do not. Rather, vague predicates apply to objects to varying degrees. As a man loses hair he becomes more and more bald; so the predicate 'is bald' applies to him more and more and the assertion that he is bald increases gradually in its degree of truth.

One serious objection to this view is that it really replaces vagueness with the most refined and incredible precision. Set membership, as viewed by the degrees-of-truth theorist, comes in precise degrees, as does predicate application and truth. The result is a commitment to precise dividing lines that is not only unbelievable but also thoroughly contrary to how we think of everyday vagueness (as noted in §1).

It is often supposed by philosophers that vagueness resides in language. One popular view here is that vagueness itself is a matter of semantic indecision (for example, Lewis 1986). On this view, all external objects, properties and relations are precise. Each vague linguistic term has a meaning which can be made precise in a whole range of different permissible ways. For example, 'over 70 years of age' is one acceptable way of making precise the meaning of the term 'old'. But other equally good ways are 'over 72' and 'over 74'. The rules that govern the use of the term 'old' are not specific enough for us to be able to choose non-arbitrarily some one precise term as capturing its meaning. When the term 'old' was first introduced, no decision was made to link it exclusively with one particular precise property. Instead it was applied widely in a range of cases, thereby acquiring a vague meaning. And what is true here for 'old' is true *mutatis mutandis* for all other vague terms.

Now if it is indeed true that there are no vague properties expressed by vague predicates, but instead ranges of precise properties, then, under some ways of making precise a vague predicate, it will definitely apply to a given object (in virtue of the object having the appropriate precise property) and, under other ways, it will not. Suppose that Alfred is 67. If 'old' is sharpened to mean 'over 70' then Alfred is not old: he lacks the precise property of being over 70. But if 'old' is sharpened to mean 'over 65', then Alfred is old - this time he has the right precise property. Is it really true that Alfred is old, then? If these two ways of sharpening the term 'old' are equally acceptable - if they both express precise properties falling in the range associated with 'old' - then the natural answer is that it is neither true nor false that Alfred is old. He is a borderline case. So, there really is no definite age at which Alfred becomes old: the boundary between being old and not being old is not sharp. By contrast, if Alfred is 97 years of age, then, under any acceptable way of making 'old' precise, he will count as old. So here it is unquestionably true that Alfred is old. And if he is 21, then, no matter which acceptable precisification we choose for 'old', he will not count as old. The claim that Alfred is old is false.

The thesis that vagueness is semantic indecision thus leads straightforwardly to the following claims. Vague sentences have three possible truth-values: true, false and ‘indefinite’ (neither true nor false). A vague sentence is to be counted as true if it comes out true under all acceptable ways of making precise its component vague terms; as false if it comes out false in every such case; and as neither true nor false if it comes out true under some ways and false under others. These claims entail that the law of excluded middle (LEM) remains true for vague sentences. So, the semantic indecision theory of vagueness provides us with a classical conception of reality (all that there is in the world is precise), a safe haven for vagueness in the linguistic realm and a conservative attitude towards the retention of LEM.

There are grave difficulties, however. In particular, it is far from clear that the semantic indecision approach fares any better than the degrees-of-truth view with respect to sorites paradoxes and robust or resilient vagueness. Another objection concerns LEM. The objection is that

(8) Either Herbert is bald or Herbert is not bald,

to take one instance of LEM, should not be counted as true if Herbert is a borderline bald man. For if (8) is true then either Herbert is bald or he is not bald. If this is the case then the question, ‘Well, which is he then?’, must surely have an answer; that is, if (8) is true then precisely one of the disjuncts in (8) must be true. So ‘Herbert is bald’ must be either true or false. This runs contrary to the assumption that Herbert is a borderline bald man. So, (8) is not true.

One common feature of both the standard degrees-of-truth approach and the semantic indecision theory is that they employ precise metalanguages in stating the truth-conditions for vague object language sentences (a metalanguage is used to talk about the object language). It is this feature which, in my view, dooms them to failure. A central aspect of the resilient vagueness of ordinary terms is that, in sorites sequences, there simply is no determinate fact of the matter about the transition from true to some other value. Any attempt to state truth-conditions for vague discourse in precise language will inevitably fall foul of this fact.

Another possible approach, then, is to start out using a vague metalanguage, which mirrors in its vagueness the object language. One proposal along these lines is based on the three truth-values, true, false and indefinite. Just as sentences in the object language can be indefinite, so too can sentences in the metalanguage (and indeed in all the higher metalanguages). If this approach is to avoid the sorites paradoxes, it is essential that it not be true that every object language sentence is true or false or indefinite. For this would create sharp dividing lines. But neither can it be false that every such sentence is true or false or indefinite. For this would require further truth-values. Instead, it has been argued that the above generalization about object language sentences must be indefinite. This permits us to hold that the claim that there is a last true sentence, followed by a first indefinite one, in a sorites sequence is indefinite. And if this is the case then sorites arguments cannot be sound (see Tye 1990).

There are many philosophers who would reject all three of the alternative proposals sketched so far. The fourth and final approach I shall mention is the epistemic view (Sorensen 1988, Williamson 1994). According to this position, vagueness is a kind of ignorance. The nonlinguistic world is precise. Standard logic holds even for vague discourse. Every molecule is either inside or outside Everest, for example. We just do not know where the boundaries lie. Likewise, there is always a single hair, the addition of which would turn a bald man into a man who is not bald, even though we cannot say which hair this is. Our sensory and conceptual mechanisms are simply not equipped to make the necessary fine-grained discriminations. Sorites arguments, then, rest upon a false premise.

This view is pleasingly straightforward. Unfortunately, it seems counterintuitive. It denies outright the existence of robust or resilient vagueness. Moreover, it seems to misconceive borderline cases. Our ordinary concept of a borderline case is the concept of a case that is neither one thing nor the other. ‘Definitely’ here does not seem to mean ‘known’ or ‘knowably’.

So, whichever way we turn, we quickly become enmeshed in difficulties. Of all the philosophical mysteries, vagueness is one of the most perplexing.

Vaihinger, Hans (1852-1933)

Hans Vaihinger was a German philosopher and historian of philosophy. Much of his work was a response to Kant's philosophy, and he contributed to the revival of interest in Kant at the end of the nineteenth century both in his published commentaries and in founding a journal and society for the discussion of Kant's thought. He developed his own philosophy, the philosophy of 'as-if', which was derived from the Kantian notion of 'heuristic fictions'.

Vaihinger was born near Tübingen in Germany. He studied theology and philosophy, graduating from the Tübingen seminary. He taught at Strasbourg and later Halle until 1906, when he retired because of failing eyesight.

In 1881 and 1892 he published two volumes of his massive *Kommentar zu Kants Kritik der reinen Vernunft (Commentary on Kant's Critique of Pure Reason)*, a detailed commentary, not only on the first seventy pages of Kant's *Critique of Pure Reason*, but also on previous commentaries. This still valuable work was never completed. However, the numerous articles that he wrote set out his views on the major sections of the *Critique* not covered in the *Kommentar*.

Vaihinger never counted himself a member of any particular school of Neo-Kantianism, but contributed to the renewal of interest in Kant. In 1897 he founded the journal *Kant-Studien* (Kant Studies). In the first issue he claimed that its purpose was to avoid partisan approaches to Kant scholarship that were prevalent in the Neo-Kantian 'school' journals and instead to provide an arena for all Kantian scholars. However, Vaihinger could be as polemical as other Neo-Kantians. In 1904 he formed the *Kant-Gesellschaft*, a society whose membership funded *Kant-Studien*.

With his retirement from teaching,Vaihinger resumed work on the philosophy of 'as-if', begun in 1876. He drew from Lange and Schopenhauer as well as Plato, Darwin and Nietzsche, but above all from Kant. It was primarily the Kantian notion of 'heuristic fictions' that led him to his philosophy of 'as-if'. In the *Critique of Pure Reason* Kant argues that although we cannot prove that the soul is a simple substance, it serves as a regulative idea: we act *as if* the soul is indivisible (see Kant, I. §8). For Vaihinger this counts as a 'fiction' and is to be distinguished from a 'hypothesis'. While we cannot always differentiate between a fiction and a hypothesis, the latter must be capable of being confirmed. Once found to be true a hypothesis loses that status. A fiction, however, can never be confirmed; its validation comes in being justified. Thus the Kantian 'fiction' that we must act as if we are free moral agents is justified by the moral actions that result from that belief. Vaihinger argued that fictions are useful in a wide range of areas. For example, the notions of the atom and the 'thing-in-itself' are important for science and metaphysics. Fictions also have consequences for religion and ethics. Reflecting his early religious training he suggested that the fiction of the 'virgin birth' is particularly 'beautiful'. And he argued that a fiction of major significance in terms of human action is to act *as if* we were morally free agents.

In 1911, Vaihinger and Raymond Schmidt founded *Annalen der Philosophie (Annals of Philosophy)* to further the philosophy of 'as-if'.

Valla, Lorenzo (1407-57)

Unlike most Renaissance humanists, Valla took a special interest in philosophy. However, his most influential writing was a work of grammar, Elegantiae Linguae Latinae (The Fine Points of the Latin Language); he had no comprehensive philosophy, nor did he write mainly on philosophy. Valla considered himself to be a revolutionary overturning received opinions, bragging that through his works he was 'overturning all the wisdom of the ancients'. His preference for Quintilian over Cicero and criticism of classical authors shocked older humanists, and religious authorities were upset by his views on the Trinity and on papal authority, but Valla never sought the overthrow of classical studies - or the papacy for that matter. He sought rather to destroy the Aristotelianism then reigning in the universities. In De Vero Falsoque Bono (On the True and False Good) (1431), he argued for the superiority of Epicureanism over Stoic and Aristotelian ethics. In De Libero Arbitrio (On Free Will) (1439), he corrected Boethius' treatment of free will and predestination. In the Dialectica (1438-9) he set out to reform logic and philosophy because he believed Aristotle had corrupted them. Asserting that Aristotle had falsified thought because he had falsified language, Valla was determined to show how logic rightly conformed to the linguistic usage of the classical literary authors; essentially Valla had aggressively revived the ancient competition between the rhetorical and philosophical traditions. The first great humanist, Francesco Petrarca (better known in English as Petrarch), had attempted something similar in the fourteenth century, but Valla's knowledge of philosophy was greater than Petrarch's and he had access to more sources. Furthermore, Valla knew Greek and could read texts which the medieval Aristotelians knew only in Latin translation.

1 Life and works

Valla was born in Rome. His family came from Piacenza, but had firmly entrenched itself in the papal bureaucracy. Valla's father, grandfather, uncles and brother-in-law all worked in the papal curia as legal and secretarial officials. His father Luca died when Valla was still a boy. His mother Caterina (Scribani) saw eight of her eleven children die young, and buried her two adult sons as well: Paolo (a friar) died in 1439, and Lorenzo on 1 August 1457. Valla never attended university, but he was fortunate enough to learn Greek. He never married but around 1450, in the space of two years, Valla had three children by a servant girl in Rome. He claimed to have done so to prove to his relatives that he was celibate by choice and not incapacity. He gave the children to his sister whose marriage had proven infertile.

In 1430, after failing to gain the position as papal secretary vacated by the death of his uncle, Valla left Rome for northern Italy. He spent time in Venice and Piacenza before becoming professor of rhetoric at the University of Pavia in early 1431. He fled Pavia, however, in the spring of 1433 because of the indignation of the law faculty at his letter attacking the ignorance of the medieval jurist Bartolo of Sassoferrato. He spent the next few years travelling about northern Italy supporting himself as a private teacher. Finally, in 1435, he joined the court of King Alfonso of Aragon, who was engaged in the conquest of the kingdom of Naples. Valla had the title of secretary, but functioned more like a scholar-in-residence. The king was generous, granting Valla temporal benefices and protection during his controversies. Valla's years in southern Italy were the most fruitful of his scholarly career. Once established in Naples (conquered by Alfonso in 1442), Valla was even able to take up teaching rhetoric again. But Valla yearned for Rome. In late 1447, after receiving favourable signs from the papal court, he returned to his native city. Pope Nicholas V (1447-55) made him a papal scribe (in Valla's case this was a sinecure) and appointed him professor of rhetoric at the University of Rome. He also generously rewarded Valla for his scholarly labours, giving him, for instance, 500 gold ducats for translating Thucydides. The next pope, Calixtus III (1455-8), made Valla a papal secretary (another sinecure) and showered him with ecclesiastical benefices, including (although Valla was not a priest) the position of canon in St John Lateran, the cathedral of Rome.

Valla provoked his first controversy in 1428 with a now lost comparison of Quintilian and Cicero, scandalizing fellow humanists by his preference for Quintilian. Valla found in Quintilian's *Training in Oratory* a lifelong guide not only to rhetoric, but also to philosophy, logic and language. Later in life, Valla claimed that he had virtually memorized *Training in Oratory*. Indeed, an awareness of Quintilian's influence is essential for a correct understanding of Valla's work.

Valla completed his first major work, the dialogue *De Voluptate (On Pleasure)*, in the early 1430s; in later

redactions he changed its title to *De Vero Falsoque Bono (On the True and False Good)*, but did not alter its Epicurean slant. The first versions of his other major works were finished while Valla was in the employ of King Alfonso.

To his most ambitious work, Valla gave the shorthand title *Dialectica*. Its full title changed with every redaction: first it was the *Re-tilling…* (*Repastinatio…*), then the *Refabrication…* (*Reconcinnatio…*) and finally the *Restructuring* (*Retractatio*) *of All Dialectic with the Foundations of the Whole of Philosophy*. For all of Valla's grand hopes, the *Dialectica* failed to galvanize Renaissance humanism. It experienced a moderate manuscript circulation and was printed separately only four times before entering Valla's *Opera Omnia* of 1540.

Elegantiae Linguae Latinae (The Fine Points of the Latin Language), on the other hand, was a huge success. With nearly seventy known manuscripts and more than 150 printed editions before 1600, the *Elegantiae* made Valla a major authority on the language. Treating a wide range of grammatical and lexicographical points, Valla took as his standard not the rules of the classical grammarians, but the actual usage of those whom he viewed as the very best practitioners of Latin: the *oratores* (specifically Cicero and Quintilian). With extraordinary erudition, Valla presumed not merely to teach his contemporaries correct classical Latin usage, but also to criticize the Latin of classical writers and grammarians. He conspicuously condemned the late ancient author Boethius as 'a Roman who did not know how to speak Roman'.

In 1440 Valla published his famous *Oratio (Oration)* on the Donation of Constantine, the document with which Emperor Constantine purportedly deeded the western part of the empire to the papacy. Numerous medieval jurists and political thinkers had denied its validity, and some had even denied its authenticity, but no one before Valla had effectively demonstrated (on the basis of linguistic, nuvmismatic and historical evidence) that this was an early medieval forgery.

Valla's *Oratio (Oration)* long remained subject to controversy. Of greater long-term significance, however, was another work Valla completed in these years: the *Collatio Novi Testamenti (Collation of the New Testament)* (called in its last redaction *Annotationes in Novum Testamentum*), where he compared the Greek text of the New Testament with the Vulgate Latin translation. Valla had no sense of the difficulties caused by the Greek tradition and focused narrowly on the peccadillos of the Latin translation instead. None the less, he showed how humanists could use their philological and historical expertise to compete as scriptural theologians with the dogmatic theologians of the medieval tradition. Valla's work had little impact in Italy, but once 'discovered' by Erasmus, the *Annotationes* became an inspiration for humanist scripture scholarship in the Reformation era.

While in southern Italy, Valla also produced works typical of Renaissance humanism. He wrote a history of the deeds of King Alfonso's father, dashed off several philological opuscula, prepared a lost commentary on the pseudo-Ciceronian *Rhetorica ad Herennium*, translated Greek classics (Aesop, Homer, Xenophon, St Basil the Great and Demosthenes), wrote invectives against fellow humanists and composed dialogues. In the first, *De Libero Arbitrio (On Free Will)*, Valla asked how free will related to divine foreknowledge, condemning Boethius for mishandling the issue out of an excessive affection for philosophy. In the second, *De professione religiosorum (On the Professing of Vows by those in Religious Orders)*, he challenged the notion that the members of the religious orders are more religious or meritorious than lay people. *De professione religiosorum* had a minimal circulation, but its boldness had a price. In 1444 Valla was called before the Inquisition. Only royal protection saved him. Subsequently, he wrote a *Defensio quaestionum in philosophia (Defence of Questions in Philosophy)* rebutting the charges of heresy and in 1444 an *Apologia* to Pope Eugenius IV.

The *Apologia* was part of Valla's campaign to return to Rome, which succeeded in late 1447. In the last decade of his life Valla continued to revise his major works, but embarked on no new large project apart from the Latin translations of Herodotus and Thucydides undertaken at the behest of Pope Nicholas V. He also entered into a lengthy literary war with Poggio Bracciolini, a leading humanist in the papal curia. Finally, in these last years, he delivered an encomium on the mystery of the Eucharist and another on Thomas Aquinas. Valla praised Aquinas as the best of the medieval theologians, although he considered Aquinas inferior to the church fathers because they did not mix theology with 'petty dialectical syllogising and metaphysical musing' nor 'make philosophy the basis of their arguments' (*Opera Omnia*, vol. 2: 350).

2 Ethics

The notion that Valla was a neo-pagan libertine is not borne out by his life and writings. The basis of that myth is the Epicureanism of *De Vero Falsoque Bono*; ironically the dialogue was principally an exercise in Christian apologetics. Valla was neither the first nor the last Renaissance intellectual to appreciate Epicureanism. In a 'moral letter' of about 1429, the minor humanist Cosma Raimondi argued that Epicureanism answered the needs of human beings as composites of body and soul much better than Stoicism. In his youth the fifteenth-century Platonist Marsilio Ficino was also much taken with Epicureanism, and in the sixteenth century Thomas More had his Utopians base their lives on the principle that pleasure was the highest good. But no one in the Renaissance argued so extensively and forcefully for Epicurean ethics as Valla (see Epicureanism §§10, 11; Stoicism §16).

In denying that happiness resided in virtue, Valla took the same position towards Stoic ethics as Thomas Aquinas (§13), and observed at the start of the that to argue otherwise would render the Incarnation otiose. By refuting the Stoics, Valla was affirming the insufficiency of human beings to achieve happiness outside the Christian dispensation, but Valla carried the argument much further than was needed to refute Stoicism. This defence of Christianity was not an end in itself. It was rather the means by which Valla was able to attack a highly respected philosophy and specifically a highly respected Christian philosopher, Boethius, the sixth-century Roman author whom Valla seems to have considered the root of medieval philosophical evil. At the end of the *De vero bono* it becomes clear that Valla's aim was to destroy Boethius' assertion in Book 4 of *The Consolation of Philosophy* that virtue was the true path to happiness.

Similarly, Valla's appropriation of Epicureanism can be seen as another means by which to discredit philosophy. Although Valla has been criticized for presenting an inaccurate picture of Epicureanism and for relying only on Latin sources, his intention was not to explain Epicureanism, but simply to use it in his campaign against philosophers. Philosophy, as he says early in the *De vero bono*, is merely a foot-soldier in the army of Queen Oratory. This is not to say that Valla failed to value Epicureanism or Christianity, but rather that neither the exposition of Epicureanism nor the defence of Christianity were his ultimate purpose.

Valla divided the *De vero bono* into three books. In the first, he had the Stoic speaker complain that all nature conspires against virtue. Animate beings spontaneously, that is to say naturally, seek pleasure and flee the pain imposed by virtue, thus refuting by their actions the famous Stoic formula that virtue is living according to nature. Taking his cue from pseudo-Quintilian (*Major Declamations* 2.1), Valla further argued that virtue actually makes us miserable, while pleasure makes us happy. Opponents of Epicureanism had traditionally charged Epicureans with having no reason for rejecting heinous behaviour if it was pleasurable (see Cicero *On the Ends of Good and Evil* 2.27). Valla agreed: at the end of Book 1, Valla had his Epicurean speaker approve of adultery, advocate free love (what Valla called 'Platonic love'), condemn virginity and present for imitation the shameless behaviour of the Olympian gods.

Book 2 presented the other side of the argument. In it, Valla proved that the moral goodness propounded by the philosophers (*honestas philosophorum*) was fraudulent. Even in their most apparently selfless actions people always act out of self-interest. Virtue consists precisely in actions which bring about this selfish advantage (*utilitas*), and actions that are not self-serving are foolish. The moral goodness of the Stoics is nothing more than empty verbiage. At the end of Book 2, the Epicurean speaker denies the immortality of the soul and reaffirms worldly pleasure as the only valid good.

Valla began Book 3 with an attack on the Aristotelian notion of virtue as the mean between two vicious extremes, condemning the artificiality of this scheme. He denied, for example, that liberality was really the mean between avarice and miserliness because the opposite of liberality is in fact a virtue, thriftiness. Earlier, in Book 2, he had the Epicurean speaker refute Aristotle's assertion that the contemplative life was the highest and happiest form of existence. In the *Dialectica* (*Repastinatio Dialectica* 75-7), Valla further attacked Aristotelian ethics by denying that prudence was a virtue, explaining that virtue resided exclusively in the will while prudence resided in the mind (see Aristotle §22-5).

Thus Valla discredited not only Stoicism and pagan Epicureanism, but also Aristotelianism. Having proved the unacceptability of all forms of philosophic ethics, he could 'condemn and damn philosophy' (*De vero bono* 271 §7) and explain that the highest good is found not in philosophy but in religion, which teaches that resistance to vice in this life means torment and death for the sake of eternal happiness in heaven, where we will enjoy the vision of God. In short, having exposed the inanity of the philosophers, Valla changed the terms of the dialogue

and moved from philosophy to theology. In the last part of the dialogue he launched into an exposition of Christian teachings on heaven and hell. In the process, he transformed Christian ethics into a form of Epicureanism, equating the delight of heaven with pleasure, the vision of God with the love of God, and love itself with pleasure (*amatio ipsa delectatio est*). That left the question of why we love God. Christianity traditionally answered that we loved God *propter se*, because of what he is. But if that were so, then the end of Christian ethics would not be pleasure, but God. Consequently, in both the *De vero bono* and the *Dialectica*, Valla insisted that we love God not as an end, but as an efficient cause, as the producer of the pleasure of heaven. Valla's Christian Epicureanism thereby ends up instrumentalizing God.

3 Free will and determinism

In *De Libero Arbitrio*, Valla once again condemned philosophy for corrupting Christian theology and attacked Boethius for leading the way. In the *Consolation of Philosophy*, Boethius had reconciled human free will and divine foreknowledge by arguing that God knows in an instantaneous 'now' what we experience as past, present and future (see Boethius §5). Valla found this explanation inadequate: his own solution was to compare God's foreknowledge to an oracle who had the power to see the future without causing it. At best, this explanation is the same as Boethius'; at worst, it is tautological.

Valla's target, however, was not really Boethius' explanation of divine foreknowledge, but his confidence in having proven human free will. While denying that God has deprived us of liberty and therefore responsibility, Valla did not know how anyone could reconcile free will with the omnipotent will of God. Citing biblical passages which suggest predestination, Valla condemned philosophers who presumed to understand 'the power and will of God'. Instead, he argued that 'we stand by faith, not the probability of reasons' (*De Libero Arbitrio* 180). Thus, when he refuted astrology in the *Dialectica*, he based his argument not on human liberty, but on divine omnipotence: God's will and not the heavens controlled human destiny. He was therefore consistent in the *Dialectica* in insisting that nothing in nature happened by chance. On the subject of divine power, he rebuked Aristotle for denying that God can make not to have happened what has already happened. The past is not immutable because that would be a limitation on divine power. Without feeling any need to develop the implications of his positions, Valla denied contingency, held that God predestined everything and insisted that there was no conceivable limit to God's power (see Free will).

4 Logic

The *Dialectica* was Valla's philosophical *summa*. Into it he poured his thought on logic, philosophy, and theology. It has two main themes. One is that logic is 'a matter indeed short and easy', no more than a subsection of the far more comprehensive discipline of rhetoric. The second and predominant one was that Aristotle and his followers had erred because they had departed from common linguistic usage (*consuetudo loquendi*). By common linguistic usage Valla did not mean what has been called ordinary language: he scorned the 'stupid' popular manner of speaking when it suited him to do so (*Repastinatio Dialectica* 55), and he had little use for the vernacular. Rather Valla meant classical literary Latin. He never stopped to give a theoretical explanation of why linguistic usage is the touchstone of truth.

Valla conceived of logic in terms of the corpus of logical texts used in the twelfth century when medieval Aristotelianism first appeared (Porphyry's *Isagōgē* and Aristotle's *Categories*, *De Interpretatione*, *Prior Analytics*, *Posterior Analytics*, *Topics* and *On Sophistical Refutations*), not in terms of contemporary logic which had moved significantly beyond Aristotle in many areas. Although Valla divided the *Dialectica* into three books, he gave half of it over to the discussion of the categories in Book 1. He did not challenge the value of the categories; his purpose was simply to reduce their number. He kept substance, the first of Aristotle's ten categories, and reduced the remaining nine (the accidental categories) to just two, quality and action, expending a great deal of effort to show how the remaining seven reflected one of these other two.

Valla also reduced six transcendental terms (being, thing, something, one, true and good) to one term, 'thing' (*res*). The transcendentals had emerged among medieval Aristotelians as a set of terms which transcended the limitations of the categories and were convertible with each other. Their number was not universally agreed upon (John Duns Scotus, for instance, recognized more than the six transcendentals listed by Thomas Aquinas and treated by Valla) and they played a minimal role in logic, but they were important in metaphysics. Valla probably seized upon the

transcendentals because the first of them, being (*ens*), provided him with a starting point for his destruction of medieval Aristotelianism. He denied that *ens* could be a transcendental since in classical Latin it was exclusively a participle, not a noun, and therefore resolvable into 'that thing (*res*) which is'. Hence *res*, and not the illegitimate noun *ens*, is the universal term encompassing all terms and all categories.

Valla also denied the validity of a whole group of abstract terms of medieval philosophy formed by the addition of the suffix *itas* to a noun or pronoun, such as *quiditas* (whatness) and *haecceitas* (thisness). These terms, Valla explained, were illegitimate because in Latin only adjectives can properly accept *itas*, an example being *bonitas* (goodness) which is formed from *bonus* (good). Since Valla also denied that Latin permits neuter singular adjectives to constitute entities in themselves (that is, *bonum* alone means not 'the good' but 'good thing'), he has sometimes been portrayed as a radical nominalist. In fact, he quite happily accepted the legitimacy of abstractions and universals if they were properly formed according to the rules of Latin. He simply ignored the metaphysical implications of his positions.

Similarly, he ignored the epistemological implications of his view of truth. He explicitly accepted the traditional correspondence theory of truth, that truth was the correspondence between what one asserts about a thing and what the thing itself is. Yet, in also making God the fount (*fons*) of truth, attributing truth to divine illumination, and asserting without further elaboration that falsity consists in the obstruction of this fount (*Repastinatio Dialectica* 20), Valla left the way open for a different approach to truth based on the absolute power of God. Consistent with his view that God can make not happen what has happened, he seems also to have held that human capacity to attain truth is circumscribed by the fact that God can change truth at any time and that the only people who know truth are those whom God chooses to illumine.

The same indifference to developing the implications of his theories appears in Valla's discussion of language. Treating the category of quality, Valla characterized signification as a quality of human utterance (*Repastinatio Dialectica* 122-4). He further explained that significant speech is a human institution: people apply 'signs' to objects. The first to have done so was Adam, who later taught these significations to posterity. Up to this point Valla hardly differed from the medieval Aristotelians, but then he suddenly dropped this line of argument and took up the relationship between 'word' and 'thing' within his scheme of categories. Though he viewed language as the touchstone of truth, Valla never bothered to develop a linguistic theory (see Language, Renaissance philosophy of §§2, 3).

At several points in Book 1, Valla discussed physics. Having no overarching physical theory of his own (apart from reliance on the criteria of common sense and linguistic usage), he only made small alterations to Aristotelian physical theory. He had no inkling of the use of mathematics in physics and no patience with geometric descriptions of nature, mocking, for instance, the notion that the earth could be treated as a mere point in space. On occasion he appealed to his own experience to correct Aristotle; in one example he cites his observation of modern bombards. He also challenged fundamental Aristotelian tenets, such as the principle that whatever is moved is moved by another. But these criticisms do not come together as a coherent whole and at times amount to very little. For instance, in rejecting the principle that whatever is moved is moved by another Valla merely referred the reader to Macrobius.

After the categories, Valla treated propositions (Book 2) and various forms of argumentation, especially the syllogism (Book 3). Though he rejected much that Aristotle said about modal propositions and modal syllogisms and though he banned outright Aristotle's third figure of the syllogism (see Aristotle §5), Aristotelian logic survived Valla's critique essentially intact. On the subject of topics, examples and enthymemes, Valla incorporated Quintilian's discussions of them from the *Training in Oratory (Institutio Oratoria)*. In sophistics, Valla was much concerned, using literary examples, to defeat the argument from *sorites* (that is, the argument from accumulation: with the subtraction of which grain of sand does a pile cease to be a pile?) and dilemma (see Vagueness §2). To defeat the latter he constructed a fictive oration in which Protagoras answers a dilemma put to him. This section alone disproves the notion that Valla was a sceptic.

The centrepiece of these pages revolves about a point of language. In Greek the marker for an indefinite proposition is *tis*, which can mean the indefinite 'some', but also the particular 'a certain'. Since Boethius, the standard translation in logic of *tis* had been *quidam*, which, Valla pointed out, means 'a certain' and not 'some'. Valla could therefore severely criticize the medieval Latin analysis of propositions and syllogisms wherever

quidam was used as an indefinite. Furthermore, he showed that whereas Greek was limited to *tis*, Latin had many words with nuanced differences to express 'some' and 'a certain', thus proving not only the superiority of Latin (a cause close to Valla's heart), but also that correct logic rested on the correct use of language.

The *Dialectica* failed to overthrow Aristotelian logic, let alone Aristotelian philosophy, and it never really confronted contemporary logic. The vast majority of humanist logicians declined to follow Valla's prescriptions. The *Dialectica* did, however, forcibly argue for the use of a natural language in logic and in this respect Valla was clearly in the vanguard of a broad drive by humanists to simplify logic and make it more amenable to rhetoric and literary practice.

Vallabhācārya (1479-1531)

A pivotal figure in the history of Indian philosophy and religion, Vallabhācārya was the last of the classical Vedānta philosophers, as well as the originator of a religious community which called for the worship of Kṛṣṇa through acts of devotion, in return for grace and deliverance from rebirth. He proposed a modification to Śaōkara's philosophy of nondualism, claiming his 'pure nondualism' better explained the relationship between the Supreme Being and the soul. For the laity, he offered a practical religious regimen called the 'path of fulfilment', through which the devotee is initiated into an individual relationship with Kṛṣṇa before proceeding to fulfil the relationship through specific personal acts of devotional worship.

Vallabhācārya (Vallabha Bhaṭṭa), born into a Tailangana Bhāradvāja Brahman family belonging to the Taittirīya branch of the Yajurveda, was an important religious leader of the later medieval period of North India. He promulgated a religious association (*sampradāya*) called *Puṣṭimārga* ('path of fulfilment'), based on the popular religious notion of selfless devotion (*bhakti*) to God, which has influenced millions and persists to the present day, especially among the mercantile communities of Gujarat, Rajasthan, Maharashtra, Harayana, western Uttar Pradesh and western Madhya Pradesh. Vallabha's life and work must be understood in the context of his times, a context influenced by popular forms of ecstatic religion and the confrontation of Islamic and Hindu thought, as well as threatened by an unstable political atmosphere.

In a sense, Vallabha was a Brahmanic or Sanskritic reaction to the challenge of being Hindu in the early sixteenth century. His birth was the culmination of a prediction that an incarnation of Viṣṇu would appear in his family after it had performed 100 soma sacrifices. His mother gave birth to a stillborn child in a forest while fleeing their home in Benares which was threatened by Muslim armies from Delhi and Jaunpur. Informed by Kṛṣṇa that the child was alive, the parents returned to find Vallabha surrounded and protected by fire. The phenomenon of fire dominates the themes of Vallabha's life. The circumstances of his birth are an obvious connection, but in addition his family were experts in the *Yajurveda*, a book of Vedic rituals and sacrifices; the basis for all Vedic rituals is fire, of which Agni is the god. For his followers, Vallabha speaks as the fire-mouth (*jvālamukha*) of Kṛṣṇa, cleansing the world of impurities. Vallabha called himself 'Vaiṣvānara' ('universal divine fire'), incarnated on earth to be a source of knowledge of the Supreme Being. Upon his death, Vallabha walked into the Ganges at Benares and disappeared in a ball of flame.

Sampradāya sources claim that an image of Kṛṣṇa, which, in 1410, had pushed its hand and arm through the ground on Mount Govardhan in Braj (the region in which Kṛṣṇa was born), suddenly erupted further at the moment of Vallabha's birth, exposing the face and uplifted arm of Kṛṣṇa as Lord Govardhananātha, the form of Kṛṣṇa which protected the people of Braj from the wrath of the rain-god Indra. It is believed that this image was a *svarūpa*, or self-manifestation, of Kṛṣṇa, and that Vallabha was the 'mouth' of the *svarūpa*. Later, Vallabha was instructed by Kṛṣṇa in a dream to proceed to Mathura, identify the half-hidden image and see to its worship. Shortly thereafter, while staying at the village of Gokul, the historic birthplace of Kṛṣṇa, Vallabha was given the *brahmasambandha* (connection to the Supreme Being) by Kṛṣṇa in a dream. The *brahmasambandha mantra*, *śrīkṛṣṇaḥśaraṇam mama* ('Radiant Kṛṣṇa is my refuge'), was an act of initiation, in which Vallabha unconditionally placed himself in the grace of Kṛṣṇa while assuming responsibility for the care and worship of the *svarūpa* of Govardhananātha, later known as Śrīnāthajī.

Vallabha believed that he lived in a time when it had become impossible for the individual to achieve spiritual liberation through study or the use of ascetic practices. Five impurities (*doṣas*) inevitably prevented the soul from realizing its connection with the Supreme Being: innate impurities; impurities resulting from one's habitation; those resulting from one's time of life; those resulting from all kinds of association; and those resulting from direct contact. The notion of impurity, and its absence being an a priori condition for spiritual progress, is an ancient principle of Brahmanism; thus, it is not surprising that Vallabha placed this notion at the centre of his liberation philosophy. Initiation into the *sampradāya* through the *brahmasambandha mantra* results in the immediate cleansing of the five *doṣas* from the soul (*jīva*).

Vallabha belongs to the Vedānta school of Hindu philosophers, which includes Śaōkara, Rāmānuja, Madhva and Nimbārka. Vallabha argued that Śaōkara's form of Advaita (monism) erroneously relied upon the notion of

māyā (illusion) to explain the apparent division or difference between the Supreme Being and the soul. He insisted that no amount of self-study or ascetic austerity could clarify the relative positions of the Supreme Being and the soul. For Vallabha, the soul's ability to discern the relationship correctly is occluded by the presence of impurities accumulated through worldly associations. Only initiation by Vallabha or one of his direct descendants, through taking the *brahmasambandha* and dedicating one's body, mind and wealth to the service (*sevā*) of Kṛṣṇa, can put one in a position to receive the grace of Kṛṣṇa. Such grace, however, is not guaranteed, as it is dispensed by Kṛṣṇa, who may bestow it at any time on whomsoever he pleases. The initiated are given a particular form of Kṛṣṇa, usually drawn from his childhood, to worship as a personal *svarūpa*. Observing this 'path of fulfilment', the initiated create the conditions in which Kṛṣṇa is likely to provide grace.

As a teacher (*ācārya*), Vallabha departed from tradition by marrying and having children. He did so in response to a command from Kṛṣṇa, who insisted that only his direct descendants would be qualified to transmit the *brahmasambandha mantra*. Vallabha's second son, Viṭṭhalanātha, greatly expanded the membership of the *sampradāya*, and elaborated the service (*sevā*) stipulated by Vallabha. He in turn had seven sons, all of whom were given *svarūpas* of Kṛṣṇa. A month before his death, Vallabha took initiation into the fourth stage of life, *sannyāsa*, completing his duty as a Brahman; the lateness of this act is interpreted as a signal to his descendants not to follow the ascetic imperative.

Value judgments in social science

Leading theorists in the social sciences have insisted that value judgments should be strictly separated from scientific judgments, which should be value-free. Yet these same thinkers recognize that social scientists are often committed to values in carrying out their work and may be motivated by moral goals of removing or remedying social conditions. From this perspective, scientific conclusions (one sort of fact) and moral commitments (one sort of value) are intertwined in scientific practices, and the question arises whether a social scientist qua *scientist makes value judgments or only makes such judgments in a nonscientific capacity. Related questions concern the role played by moral, social, and political values in the pursuit of scientific knowledge and the impact of these values on scientific theories and methods.*

1 The values question in classical social science methodology

Émile Durkheim (§2) (founder of academic sociology in France and a pioneer of the discipline) believed that sociology, as a science, must not be contaminated by value judgments (Durkheim 1895). 'Social facts' alone have a legitimate role in sociological explanation, and the scientific explanation of a social phenomenon seeks only its efficient causes. None the less, Durkheim maintained that a scientific sociology could help determine the appropriateness of moral values and practices for societies by showing which values best promote human happiness and social solidarity. He thought a science that examines society should regard its work as incomplete unless it established a 'science' of morality (comprised of what is 'generally accepted' in a culture), and he therefore moved freely from social facts to embedded moral values and from the scientific study of morality to moral judgments. In this way, a social science delivered practical results.

Max Weber (§2) resisted such linking of science and valuation, arguing that there must be an 'unconditional separation' between empirical facts and the evaluation of those facts (Weber 1949). He viewed facts and values as 'entirely heterogeneous'. He maintained that the social scientist must shun evaluative commitments that might bias scientific work. None the less, Weber agreed with Durkheim that moral and other values are of the highest importance in social life, and Weber recognized that facts and norms are intertwined in several ways in the 'praxis' of social science. For example, scientists choose research projects based on cultural values, and in carrying out science they dedicate themselves to values of honesty and accuracy.

Weber's recommendation of a value-free social science was immensely influential, eventually becoming the orthodox position in the social sciences and philosophy. His recommendation also promoted the view that the judgments of science are demonstrable, that value judgments are not, and that scientific judgments therefore have a superior epistemological status. However, these ideas, which grew out of early sociology, enjoyed less currency in other quarters. For example, many economists and political scientists doubted from the start that a value-free model suits their 'value-impregnated' fields (see Economics, philosophy of §2). Many questions persist about whether the value-free ideal is possible or desirable, and about whether social scientists can or should avoid value judgments in their work.

2 The model of a value-free social science

Weber's distinction between praxis and methodological principle illuminates this dispute: the critics of value-free science tend to point to values present in social scientists' practices and role in society, whereas proponents argue primarily from the methodological principles and ideals of science. Weber himself was not concerned about the evaluative criteria underlying and motivating scientific practice, but with the justification of scientific conclusions. He emphasized the logical independence of facts and values and the validity of scientific methods.

The central premise in the model of a value-free social science is that the truth or falsity of scientific hypotheses and the scientific methods used to determine truth or falsity are independent of value judgments. The model presupposes the defensibility of the distinction between facts and values, but is not dependent upon any particular interpretation of the nature of a fact or the nature of a value. It also does not depend on any particular view about whether value judgments are true or justifiable, though some proponents have argued that value judgments are neither rationally justifiable nor true. Nor need the model incorporate any form of scepticism about either facts or values.

The central premises commonly found in attacks on this value-free model are the following:

1 Science presupposes values such as truthfulness, knowledge, explanatory power, and criteria that distinguish good from bad theories and explanations.
2 In selecting a problem for scientific study, values drive the process of selection.
3 All scientists have evaluative viewpoints that inevitably affect how they interpret and report their findings, including how they construct the evidence and the importance they give to some evidence to the exclusion of other evidence.
4 Whenever scientists accept hypotheses, they make a value judgment that sufficient evidence supports the hypothesis; this judgment does not follow exclusively from the scientific method, because no hypothesis is ever fully verified by that method.
5 A scientist who accepts funding from institutions whose values control the funding tacitly accepts the values and priorities of those institutions.

Value-free conceptions of scientific method and explanation must resolve these problems. Proponents typically argue that the values mentioned are pre-scientific considerations external to the science itself; they believe that observation, explanation, and theory construction are not affected by such contextual matters. However, the intermixture of facts and values in the actual conduct of scientific research makes it difficult to establish clean lines of separation, if indeed they are separate.

3 Problems of motivation and selection

One challenge to a value-free social science comes from the moral and political motivations of scientists, for example, their desire to see protection increased for vulnerable members of society or their ambition to increase the reputation of their institution. These moral and social commitments influence the selection of research topics as well as the way the results of research are interpreted, reported, and applied. Social scientists also report their results selectively, typically in a manner that supports their hypotheses and viewpoints. What will be undertaken in studies, how it will connect to social policy, and what can be accepted as a scientific answer all depend on an evaluative framework.

From Weber to the present, defenders of value-free science have not denied that knowledge is selective, influenced by values, and motivated by social concerns. The question, from the value-free viewpoint, is whether these background or extra-scientific features of work in science are relevant to questions of methodology and whether they infect the science. Underlying motives seem to defenders of value-freedom to have no direct bearing on the science. They maintain that when scientists who are motivated to demonstrate *x* obtain results from their studies demonstrating *not-x*, they report their results accordingly, if they are good scientists. Scientific methodology, from this perspective, is consistent with moral motives and value-driven selection that play a vital role but can be set aside in scientific practice.

The proponents of value-free science acknowledge that selectivity, like standards of accuracy, is a filtering device essential to good science. But they insist that the evaluative character of selectivity does not by itself taint the data or the reporting of data. This contention moves the issues from selectivity in general, to the question of whether selection involves some form of bias or failure to be impartial.

4 Problems of bias and partiality

Rigour in the design of studies to eliminate or minimize bias is a canonical principle. In general, a bias is a deviation of a finding from the truth. Many processes in the collection, interpretation, review, and publication of data can cause bias. However, bias is often difficult to pinpoint, and the term ‘bias’ is used in different senses in these discussions.

One sense of bias is distortion in an alleged finding due to a limitation in the design of the study. A biased sample, for example, may cause a problem in the generalizability of findings. Unless the sampling method ensures that all members of the reference population have a chance of selection in the sample, bias may occur. For example, some early surveys of ‘lesbian behaviour’ were limited to small samples of lesbians encountered in bars. This sample is biased if generalized to all lesbians; it may also convey negative impressions of this diverse community of women. Similarly, an early study of gay men used a sample entirely comprised of gay men in psychiatric therapy.

Many methodologists believe that scientists rarely, if ever, eliminate all biases from their studies. These methodologists propose not the complete elimination of biases, but a reporting of them wherever they can be ascertained (the reverse of so-called ‘reporting bias’, which involves a selective suppression of information). They insist that risks of bias can be minimized in well-designed research, but no method can eliminate bias or ensure that it will not be present. In the ideal, social science is free of bias in this sense, but in practice it almost always falls short.

A second sense of bias is maintaining a personal point of view that distorts the answers scientists give to the questions they investigate. This use of bias refers to a lapse of impartiality or partisanship. Partiality results from a value-directed departure from accuracy, objectivity, and balance, not merely an inadvertent distortion of facts or a limitation in sample selection. Bias of this sort can be a factor in research design, critical analyses, the interpretation and publication of results, and in peer review. Again, a basic methodological principle is that protection against partiality be built into research design, but should this prove impossible, one strategy is to disclose the personal values and how they might affect study results and reports.

Partiality should be distinguished from legitimate forms of opinion and appraisal. Partiality occurs only if there is a value-directed departure from accuracy and objectivity. If, for example, a social scientist fails to notice that an accidental omission has distorted a crucial part of a study, the distortion results from error, not partiality. A bias in the second sense is present only if distorted information is causally connected to the investigator’s values.

5 Problems of advocacy and strength-of-evidence judgments

Charges of bias can arise when a social scientist has adopted an advocacy role or has been employed to represent a particular institutional or special-interest point of view. For example, social scientists who have identified hazardous conditions, criminal activity, government neglect and the like, and who serve as experts on such matters sometimes become advocates who propose interventions and control measures. In practice, these recommendations often develop from patterns of empirical evidence that the advocates may or may not have generated themselves. These scientists apply causal criteria to the findings of studies and then make judgments about causes (of poverty, say) that are inextricably bonded to their recommendations.

Although appropriate to and required of social scientists in some roles, such as those of public health officials, advocacy is a threat to scientific objectivity whenever a group such as a government bureau, a labour union, industrial management, or a public interest group has sponsored the research. Social scientists who view themselves as social architects, using their own research to achieve what they consider a noble goal of eliminating all putative causes of human poverty, distress, disease and the like, are commonly viewed with scepticism by colleagues.

However, advocacy does not necessarily impugn either the underlying science or institutional and social policy recommendations based on it. Being loyal, dedicated, or even partisan is not equivalent to a loss of impartiality about scientific conclusions, although such participation does threaten impartiality. Partisan or institutionally loyal social scientists can, in principle, restrain or even completely eliminate their commitments in conducting a study and reporting its findings. Advocacy is also sometimes distanced from the conduct of research. For example, scientists may be advocates for the funding of research and for particular types of research needed to address what they consider unanswered research questions.

Related to problems of advocacy are problems of strength-of-evidence judgments that depend upon what is morally at stake. The social consequences of making a mistake in assessing evidence are very serious in some cases, minimal in others. These social consequences can and often do affect judgments about the strength of scientific evidence. Judgments that the evidence is sufficient and that a hypothesis should be accepted often depend heavily upon context consequences. For example, consider a study designed to determine whether women who receive state welfare payments can be deterred from becoming pregnant or, if they become pregnant, from giving birth to their child, by depriving them of increased financial aid assistance. The research is to evaluate a deterrent effect by examining the impact of a state-mandated, child-exclusion provision on fertility and birth rates among women. No prior evidence was sufficient to answer this question. Hypothesis acceptance in this study will almost certainly be contingent upon value judgments about what the consequences of acting on the evidence would be for both pregnant women on welfare and state officials.

The idea that degrees of scientific evidence are free of interpretation is challenged by this argument (which was first advanced by Richard Rudner 1953), because 'strength of evidence' is itself a value-impregnated notion. It seems impossible to give responsibility for judgments about strength of evidence exclusively to public officials, contractors, or employers, because it is the business only of a scientist, not someone else, to make a judgment about the strength of scientific evidence and about whether a scientific hypothesis is adequately supported.

6 Professional codes of conduct

Social science research can never be a morally neutral activity as long as it involves human research subjects. Many problems of value judgements in social science concern how these subjects may permissibly be used. The book *A Time to Speak: On Human Values and Social Research* (1968) by Herbert Kelman, combined with a number of controversial cases of abuses of subjects by social scientists, alerted scientists in the late 1960s to a variety of problems in research ethics. Careful attention was subsequently paid to the moral judgments that social scientists do and should make in carrying out their research. Problems stem from practices such as the experimental deception of subjects, the collection of data on persons in an individually identifiable form, and the use of financial incentives to obtain subjects.

Two types of value judgments merit attention in this context. The first type involves moral assessments of the protocols and the behaviour of social scientists. The second type concerns methodological evaluations of research practices (similar to those previously discussed). Methodological criteria govern how a procedure is to function in a research design in order to avoid screening out effects that could render the results ungeneralizable, or perhaps unreliable or of very limited generalizability. A procedure may satisfy criteria of methodological adequacy and be morally unjustified; or the procedure may be morally justified but methodologically inadequate. Here we encounter methodological-moral dilemmas. Sometimes methodological rigour is sacrificed to yield a moral gain, and sometimes moral rigour is sacrificed to yield a methodological gain (for example, by waiving a consent requirement for research involving deception).

Value judgments here intersect in several ways. A design adequate to achieve the objectives of a research protocol is generally considered a necessary condition of the moral justifiability of the research. Many argue both that it is irresponsible to use valuable resources to conduct methodologically flawed research and that it is morally unjustified to conduct research that presents risk to subjects if the research design is defective. Both claims presume criteria for assessing the methodological adequacy of research procedures, and in both cases the reasons for making methodological soundness a condition of moral justifiability are independent of these criteria.

The aforementioned normative rule that study bias must be avoided sometimes contingently conflicts with moral and professional obligations to protect the rights of research subjects. For example, because the validity of a study and the availability of funding to conduct it may be adversely affected by a poor response rate, potential subjects are sometimes encouraged to participate by repeated telephone calls and aggressive follow-ups. This badgering may fail to respect the decisions of subjects and violate their right to privacy. The point is that choices between alternative study populations, control groups, interviewing procedures, and approaches to minimizing the likelihood of bias will involve both ethical and methodological values.

Most professions arguably have an indigenous professional morality with precepts governing research ethics. These precepts specify responsibilities to research subjects, responsibilities to society, responsibilities to employers and funding sources, and responsibilities to professional colleagues. Particular codes developed for professional associations of social scientists are usually attempts to discover, formulate, and develop this inchoate morality rather than attempts to apply some general ethical theory. However, philosophical ethics has been explicitly used in some cases to help in developing this professional morality. Many social scientists have recognized that there are serious problems with attempts to base professional ethical standards entirely in practice standards, that often do not exist within the relevant field, group, or profession. If practice standards are deficient, ethical theory may be a valuable resource for reflection on, criticism of, and reformulation of the standards.

Value, ontological status of

We evaluate persons, characters, mental states, actions, inanimate objects and situations using very abstract terms such as 'good', 'unjust' and 'beautiful', and more concrete terms, such as 'courageous', 'cruel' and 'crass', drawn from fields such as aesthetics, ethics, politics and religion. Do these evaluations ascribe value properties to the entities evaluated? If so, what are these properties like? If not, what are we doing when we evaluate?

The simplest way to understand ethical discourse is by analogy with ordinary fact-stating discourse. An ethical judgment is to be understood as either true or false, being true if the situation it describes obtains, false if it does not. If ethical judgments are fact-stating, then it is natural to take evaluative vocabulary such as 'is good' and 'is courageous' as picking out properties of the entities which are evaluated.

What are these value properties like? First, we need an account of how properties are different from other kinds of entities. Then we need to decide whether values are natural or non-natural properties, where natural properties are the proper subject matter of the various sciences. G.E. Moore in *Principia Ethica* (1903) argued that goodness is a *sui generis* non-natural property. In contrast, many have tried to conceive of value properties as natural, principally by defining evaluative vocabulary in terms of the psychological states of some subject or subjects in certain conditions. By varying the state, subject and conditions, numerous such accounts can be obtained; for example, 'is good' might mean 'is desired by the speaker here and now' or 'is something we would desire to desire….in conditions of full imaginative acquaintance'.

Mackie (1977) thinks that our ethical discourse commits us to the existence of value properties which he calls 'objective values'. But he argues that such values would be non-natural, Moore's property of goodness vividly illustrating their 'queerness'. Our knowledge of them would be unexplained and, since ethical judgments are automatically motivating, these values would have a mysterious action-guiding force, quite unlike natural properties. Thus Mackie adopts an error theory of our evaluative discourse. There are no objective values. Since every ethical judgment commits us to such values, they are all false. His diagnosis of the error draws upon Hume's projectivism (see Projectivism). In truth, there is only the world of natural properties and our affective reactions to it, such as moral approval and disapproval. But we project such reactions back onto the world and speak as if it contained properties, such as goodness and badness, which merit the reactions.

Denying the existence of objective values need not force one to accept the error theory, for one can deny Mackie's conceptual claim that our ethical discourse says that there are objective values. Instead, one can think of this discourse as having an expressive, as opposed to a descriptive, function. Ayer's emotivism is an early version of this idea (see Emotivism). It is too crude, however, because it merely says that ethical judgments serve to express our affective reactions, failing to explain how it is that ethical discourse appears so similar to genuine descriptive discourse. After all, we are happy to say that ethical judgments are true or false, we engage in ethical argument to determine the correct answers to our ethical questions, we presume to persuade others to abandon their mistaken views and we acknowledge that our current ethical opinions may be wrong. Each of these features of our ethical practice tempts us to think that there is a realm of ethical facts which constrain the practice, facts which we aim to describe with our ethical discourse.

Blackburn's quasi-realist project (1984; 1993) attempts to explain the shape of our ethical practice on the basis of its expressive function. He argues that our ethical discourse is all right as it is, for, despite the appearances, it contains no erroneous commitment to objective values. Blackburn insists that we express, rather than describe, our affective reactions when we make ethical judgments. But one should ask whether a sharp line can be drawn between expression and description and, in turn, whether there is much to choose between Blackburn's position and the view which takes values to be natural properties involving our psychological states.

Mackie and Blackburn share the conception of the natural world as the world of science, which exists independently of human sensibility. A real entity belongs to the natural world, and values are not real. But perhaps this is too restrictive. McDowell (1985) has argued that values should be compared with secondary qualities, such as redness (see Secondary qualities). It is a conceptual truth that an object is red if and only if it would look red to appropriately receptive subjects in appropriate conditions. Thus redness is a dispositional property which is

conceptually connected to human sensibility, and so cannot belong to the natural world. But, since an object can possess this disposition independently of any particular experience, we are happy to think of an object as really being red, its looking red to us in the right conditions being perception of the redness which it possesses. Analogously, McDowell urges that a value, such as goodness, is to be thought of as a dispositional property of objects which is conceptually connected to an affective reaction in the right subjects in the right conditions. Again, such a value is not part of the natural world, but it is nevertheless real, the relevant affective reactions detecting its presence. If all this is right, one can argue against Mackie that our ethical discourse only commits us to the reality of values in the weak sense that their existence is independent of any particular experience. The appropriateness of the analogy between values and secondary qualities is fiercely debated. In particular, one ought to question whether any sense can be made of a perceptual route to values, especially when our affective states are often reactions to imagined or described situations, not perceived ones.

Values

The theory of value has three main traditions: subjectivism, which holds that the only valuable goods are subjective states of sentient beings; objectivism, which claims that while values must be human-related, they exist independently of us; and Neo-Kantian rationalism, which suggests that value is postulated on the basis of practical reason. Central distinctions in the theory of value are between subjective and objective values, instrumental and final values, intrinsic and extrinsic values, organic unities and the idea of an ultimate or architectonic value. There are also distinctions drawn between different types of value, such as moral and aesthetic value.

The theory of value has been neglected within Anglo-American analytical philosophy. However, recent philosophy has seen a revival in value theory. The *subjectivist* school remains the dominant orthodoxy, but recent philosophy has seen the development of new forms of *objectivism* and an increasing emphasis on value theory within the *Neo-Kantian rationalist* tradition, a tradition which does tie an account of value directly to a theory of practical reasoning.

Subjectivists assert that the only valuable goods are subjective states of sentient organisms. ‘Subjective’ can be given a wide reading to include the essential interests of a subject; on a wide definition of subjective value even the conditions necessary for the flourishing of an organism can be included in the definition. Here, as elsewhere, ‘subjective’ and ‘objective’ accounts of the subject matter shade into each other. Thus, utilitarian theories of value have evolved from Bentham’s simple hedonism, via revealed preference theories, to definitions of the valuable in terms of what is objectively good for people (see Hedonism; Perfectionism; Rationality, practical; Utilitarianism).

Objectivists claim greater degrees of independence between values and human interests and concerns. Moderate objectivists would concede that value is an anthropocentric category, and that their list of the good things in life must relate to human concerns. However, they would insist that these components of a good life are preferable because they are good, and not vice versa (see Good, theories of the §5). Extreme objectivists argue that value is not a category distinctively attuned to human concerns but exists independently of human interests. Is biodiversity, for example, good in itself? Or is it good only relative to our interests (see Environmental ethics §2)?

Neo-Kantian rationalists offer a third approach to the nature of value. They argue that subjective interests give rise to reasons, which are then subjected to formal tests to see if they are sufficient to bring about the ends they prescribe for an agent. If the reason passes these tests, the end is taken to be valuable. This theory views the connection between practical reasoning and value differently from its rivals; practical reasoning does not solely work out the means to pre-given ends but also establishes which ends are worthy of choice.

Something may be valued in itself, or for the contribution it makes to achieving a further state which is valuable. Jogging may be tedious, but it is instrumental in achieving health, which is finally valuable as an end in itself. This distinction between the instrumentally valuable and the finally valuable is properly located within the theory of practical reasoning, since it concerns the place of an ‘end’ or goal within an agent’s system of practical ends. (Thus it is sometimes called the *means/ends* distinction - see Practical reason and ethics.)

It ought not to be confused with a related distinction, properly located within the theory of value, between *intrinsic* and *extrinsic* values. There are philosophically motivated arguments for collapsing these distinctions, but keeping them apart avoids begging the question against those who, for example, believe in final ends which are extrinsically valuable. It has been argued that Kant’s theory of happiness, for example, sees it as an extrinsic value which is none the less our final end (see Kant, I. §11).

The idea of intrinsic value has been explained in many different ways. A central line of thought, found in G.E. Moore, is that intrinsically valuable things are the source of their own value whereas extrinsically valuable things derive their value from another source; intrinsic value is grounded on, but not reducible to, the ‘natural’ intrinsic properties of the object (see Moore, G.E. §1; Supervenience). Another proposal is to explain the grounds of intrinsic value via the idea of *organic unity*. Combinations of valuable things can form ‘organic’ wholes whose value is greater than the sum of the value of their component parts. The same was argued to be true of combinations of valuable with disvaluable or ‘indifferent’ things. For example, harming a sentient creature is bad,

but taking pleasure in doing so much worse.

Many philosophers have argued that values collectively have a structure and that *higher* values can be discerned which organize the entire system of value and are therefore most worthy of choice. Examples would be Aristotle's belief that contemplation was the best and most self-sufficient good that made human life as a whole worthy of choice and the similar role Kant attaches to the good will (see Aristotle §§21, 26; Eudaimonia).

How is *moral value* to be demarcated from other forms of value? One, admittedly controversial, criterion is to relate the nature of value to the test of convergence. If qualified experts converge in the making of a judgment, that is enough to sustain a 'thin' model of objectivity, which may perhaps offer a sufficient account of aesthetic values. There is no more to aesthetic value than being the fit object of such convergent judgment. However, in the moral case one requires the further feature that competent judges converge in judging a case to be, say, cruel in virtue of the fact that it is indeed cruel. In this latter case there is indispensable reference to the property, anthropocentric but real, which merits the response. This method of demarcation would have the advantage of explaining why it is internal to the practice of aesthetic judgment that a plurality of such judgments is inherent in the subject matter and can rationally be tolerated. However, this is not so in the moral case, where divergent judgment invites correction.

Vasubandhu (4th or 5th century AD)

An Indian Buddhist philosopher of the fourth or fifth century, Vasubandhu was a prolific author of treatises and commentaries. Best known for his synthesis of the Sarvāstivāda school of Abhidharma, he was sympathetic with the Sautrāntika school and frequently criticized Sarvāstivāda theory from that perspective. Vasubandhu eventually became an eminent exponent of the Yogācāra school. He also wrote short treatises on logic that influenced Dignāga, traditionally said to have been his disciple.

Probably the most original of Vasubandhu's philosophical works are his two short works in verse, known as the Viṃśatikākārikāvṛtti (Twenty-Verse Treatise) and the Triṃśikākārikāvṛtti (Thirty-Verse Treatise). In these two works, he argues that one can never have direct awareness of external objects, but can be aware only of images within consciousness. Given that some of these images, such as those in dreams and hallucinations, are known to occur without being representations of external objects, one can never be certain whether a given image in awareness corresponds to an external object. Because one can never be sure of what is externally real but can be sure of internal experiences, he concludes, a person seeking nirvāṇa *should focus attention on the workings of the mind rather than on the external world.*

1 Life and works

The earliest and the most complete biography of Vasubandhu was compiled by Paramārtha (499-569), a Chinese Buddhist pilgrim monk. It is preserved in the Chinese Buddhist canon. Some information can be gathered also from Tibetan biographies by Bu ston (1290-1364) and Tāranātha (1575-1634). The Tibetan biographies, however, differ in many points from Paramārtha's work. The available data from the various sources have been collected and studied by Erich Frauwallner.

According to Buddhist tradition, Vasubandhu was born in Peshawar, now part of Pakistan. Early biographers claim that he was initially a follower of the Sarvāstivāda (also known as Vaibhāṣika) school of Buddhism, later switched his allegiance to the Sautrāntika school and finally was converted to Mahāyāna by his elder brother Asaōga, a founder of the Yogācāra school. Modern scholars have been divided on the questions of his date and which of the many works attributed to him are really of his authorship. Frauwallner argued (1951), on the basis of discrepancies within the Chinese and Tibetan biographies concerning Vasubandhu's dates, that there were two influential Buddhist philosophers named Vasubandhu who became conflated by Paramārtha. According to this hypothesis, the earlier Vasubandhu lived in the fourth century and was the younger brother of Asaōga; he wrote numerous extensive commentaries on Mahāyāna scriptures, especially those associated with the Yogācāra school. The later Vasubandhu, according to Frauwallner, was the author of the *Abhidharmakośa* and lived in the late fifth century: it was he who wrote several short Yogācāra treatises and short works on logic and trained Dignāga, who eventually became best known as a logician. Frauwallner's hypothesis was quickly disputed by P.S. Jaini (1958) and has since been disputed by other scholars as well. Although the issue has not been definitively settled, Frauwallner's once-influential hypothesis has become decreasingly accepted by specialists in Vasubandhu's philosophy, although it still has adherents among prominent specialists in the history of Buddhist thought. This controversy has no bearing on the discussions that follow, since all scholars on both sides of the debate agree that the texts discussed below were by the same author.

2 Contributions to Abhidharma theory

One of the most influential texts in all of Indian Buddhism is Vasubandhu's *Abhidharmakośa*. According to the author's own explanation of the title, the text is comparable to a scabbard (*kośa*) from which one extracts the sword of wisdom, which is the means by which one cuts through delusions and attains the highest reality (*abhidharma*), namely *nirvāṇa*. The central argument of the book is that all complex entities are, by the very fact that they are complex, less stable and therefore less capable of providing satisfaction than simple entities. Therefore, one seeking satisfaction should focus the attention on simple objects rather than on complex entities. Examples of simple objects are the basic building blocks of experience, namely the basic qualities such as colour and shape that are apprehended in vision, sounds that are apprehended by hearing, the various qualities apprehended by the other external senses, and the moods and emotions apprehended by the mind. Examples of complex objects are houses, chariots, people and all the various things that one tries to acquire or to influence.

Another example of a complex object is that which we take to be at the centre of all experience, the self.

Much of the *Abhidharmakośa* is dedicated to showing how a world constructed only of causally related qualities can function in the absence of a substantial substratum; the world is a world of properties (*dharma*) but not of property-owning (*dharmin*) substances. The work is divided into nine chapters. The first deals with a catalogue of the *dharmas* that form the content of all experience. The second discusses sense faculties and various other faculties of living beings. The third discusses the cosmos and its various populations. The world, it is argued, derives not from a single source but from the combination of the karma of billions of sentient beings; so karma becomes the subject matter of the fourth chapter. Karma is action that arises from latent patterns of habit; these habitual tendencies are discussed in detail in chapter five. People who eliminate negative, destructive habits become noble persons, who are classified in the sixth chapter. Nobility of character is a function of correct understanding, discussed in chapter seven. Since knowledge arises through skill in meditation, meditation is the subject of the eighth chapter. The ninth chapter, which may originally have been an independent treatise, recapitulates a series of arguments against a substantial basis for our sense of personal identity and individuality.

The *Abhidharmakośa* is a text written in verse, to which the author wrote an extensive prose commentary. The verse text presents a straightforward account of cosmology and psychology as taught by the Vaibhāṣika school of Buddhism. The prose commentary, however, examines these doctrines more critically. Since the author often goes into considerable detail about various positions that Buddhist philosophers of different views presented in the past, the work is an invaluable source of information on the controversies among Buddhists and between Buddhists and non-Buddhists during the first few centuries AD. Vasubandhu often, but by no means always, sides with critics from the Sautrāntika school of Buddhism. One of the salient characteristics of this school was a tendency to regard most Buddhist theories as merely provisional or heuristic doctrines, aimed not at giving a definitive account of the inner and outer worlds but at providing a framework within which the realities of these worlds can be discovered. Because the Sautrāntika school tended to be doctrinally more fluid than the relatively rigid orthodoxy of the Vaibhāṣika school, it is often seen as a conceptual bridge leading from the more conservative schools to the Mahāyāna movement. Owing to its comprehensive nature and to its serving as a propaedeutic for Mahāyāna philosophies, the *Abhidharmakośa* became a cornerstone of the curriculum at Indian Buddhist universities such as the one at Nālandāmonastery. It is still common for Tibetan scholastics to devote five to eight years of their training to a thorough study of the *Abhidharmakośa* before going on to study Mādhyamika and Yogācāra philosophy. The text was also central to Buddhist scholastics in China. All told, it was as central to medieval Buddhist education as Aquinas' *Summa theologiae* to medieval Christian scholastics in Europe.

3 Contributions to Yogācāra

The early Buddhists discussed different worlds of experience, by which was meant different ways of experiencing the world. The 'foolish masses' of unreflective people are preoccupied with pleasures of the senses, so they are said to live in the realm of desire. More reflective people see sensible objects without hankering after them as much as unreflective people, so they are said to live in the world of appearances, by which it is meant that they perceive what appears to the senses without desiring them or despising them. People who abstract their attention away from sensible objects altogether are said to live in the world of nonappearance. While all these beings may live side by side in the same physical world, their subjective experiences of the world are radically different. Taking this commonplace observation as a point of departure, Vasubandhu argues in his *Viṃśatikākārikāvṛtti (Twenty-Verse Treatise)* and *Triṃśikākārikāvṛtti (Thirty-Verse Treatise)* that every sentient being is in a sense locked within its subjective world and has no direct contact with the external physical world. That there is an external world can be known through inference only, not through direct cognition. All experience, in other words, is mediated through one's habitual ways of seeing things. What makes one person's experience of physical circumstances different from another person's experience of those same circumstances is not the circumstances themselves; rather, it is the moods, emotional tendencies, memories and associations that each person uniquely brings to the circumstances.

One of Vasubandhu's arguments for this conclusion is that beings who experience the torments of hell cannot actually be in a physical setting of the sort described in descriptions of the hells. Those reports speak of guardians and beasts that prowl environments with heat of unbearable intensity and torment the inhabitants of those regions. But reason shows that these hell-guardians cannot themselves suffer from the conditions that the victims of hell

find intolerable. If the guardians suffered as much as the inmates, they would be so overcome with pain that they would not be able to perform their task of tormenting the captives. Therefore the guardians and beasts, and indeed all the other torments of hell, must be purely subjective experiences that cannot have an objective counterpart in the external world, no matter how intensely they are felt.

Vasubandhu observes that when our senses are capable of presenting us with experiences of things that are not really as they are experienced, our only recourse to correct the presentations of the senses is reason. But reason also lets us down. Reason, for example, provides us with the notion of atoms, that is, bits of matter that are tiny to the greatest possible extent. Reflection, however, shows that the concept of atoms leads to inconsistencies. If an atom is really ultimately tiny, then it cannot be made up of parts that are physically smaller than the atom itself. If the atom has no parts, then the region of space occupied by the atom can have no subregions; there can be no upper region or lower region or eastern region and so on. If that is true, then the atom can occupy no space at all. If one atom occupies no space, then several atoms added together cannot occupy any space. Therefore what reason presents to us, namely that a macroscopic object is a complex of a very large number of ultimately small component parts, cannot really be the case after all. The atom, then, is a concept to which nothing in the real world can correspond.

If neither the senses nor reason can provide reliable pictures of external reality, we have no reliable means of knowing what the objective basis of our experiences is. When one thoroughly understands that a sentient being can never be aware of anything but its own awareness, says Vasubandhu, full attention can be turned to those subjective factors that give experience its flavour. Distracted neither by the appearances of the senses nor by the conceptual categories of reason, one gives up either hankering for or dreading what experience provides and one cultivates a bare attention to experience. This bare attention becomes an experience that is ‘unthinkable, healthy and stable’. This is the experience of liberation or *nirvāṇa*.

Along with texts by Asaōga and Sthiramati, Vasubandhu’s Yogācāra treatises became the textual foundation for much of scholasticism in both China and Tibet. Given the central importance of both the *Abhidharmakośa* and his Yogācāra writings, Vasubandhu had an influence on Asian Buddhism second only to that of the Buddha himself.

List of works

Vasubandhu (4th or 5th century AD) *Abhidharmakośa*, ed. and trans. L. de la Vallée Poussin, *L’abhidharmakośa de Vasubandhu*, Paris and Louvain: Paul Geuthner, 1923-31, 6 vols; repr. Brussels: Institut belge des hautes études chinoises, 1971, 6 vols; trans. L.M. Pruden, Berkeley, CA: Asian Humanities Press, 1988.(La Vallée Poussin’s is still the best translation available of this key work from Vasubandhu’s phase as an Abhidharma scholar; Pruden’s translation, from La Vallée Poussin’s French, is to be used with great caution, but is the only one available in English.)

Vasubandhu (4th or 5th century AD) *Karmasiddhiprakaraṇa*, trans. S. Anacker, ‘A Discussion for the Demonstration of Action’, in Anacker, S. 1984; trans. E. Lamotte, ‘Le Traité de l’acte de Vasubandhu. *Karmasiddhiprakaraṇa*’, *Mélanges chinois et bouddiques* 4: 151-288, 1936.(A work from Vasubandhu’s Yogācāra phase in which he criticizes Sarvāstivādin views of the mechanics of ethically charged actions and their fruitions.)

Vasubandhu (4th or 5th century AD) Madhyāntavibhāgaśāstra, trans. S. Anacker, ‘Commentary on the Separation of the Middle from Extremes’, in Anacker 1984; trans. T. Kochumuttom, ‘Discrimination Between Middle and Extremes’, in Kochumuttom, T.A. 1982.(An important work from the author’s Yogācāra phase.)

Vasubandhu (4th or 5th century AD) *Pañcaskandhakaprakaraṇa*, trans. S. Anacker, ‘A Discussion of the Five Aggregates’, in Anacker 1984.(An analysis of the classes of characteristics that constitute the physical body and the mentality of human beings.)

Vasubandhu (4th or 5th century AD) *Trisvabhāvanirdeśa*, trans. S. Anacker, ‘The Teaching of the Three Own-Beings’, in Anacker 1984; trans. T. Kochumuttom, ‘A Treatise on the Three Natures’, in Kochumuttom 1982; trans. F. Tola and C. Cragonetti, ‘The *Trisvabhāvakārikā* of Vasubandhu’, *Journal of Indian Philosophy* 11: 225-66, 1983.(A seminal work in early Yogācāra theory.)

Vasubandhu (4th or 5th century AD) *Triṃśikākārikāvṛtti*, trans. L. de la Vallée Poussin, along with the

Viṃśatikākārikāvṛtti and a Chinese commentary by Xuanzang as *La Siddhi de Hsuan-tsang*, Paris, 1928-48, 3 vols; trans. S. Anacker, 'The Thirty Verses', in Anacker 1984; trans. T. Kochumuttom, 'A Treatise in Thirty Stanzas', in Kochumuttom 1982.(An important Yogācāra treatise; La Vallée Poussin's French translation is excellent and well annotated.)

Vasubandhu (4th or 5th century AD) *Vādavidhi*, trans. S. Anacker, 'A Method for Argumentation', in Anacker 1984.(One of the earliest Buddhist works on debate and logic, later criticized by Dignāga, whose work on logic superseded Vasubandhu's.)

Vasubandhu (4th or 5th century AD) *Viṃśatikākārikāvṛtti*, see *Triṃśikākārikāvṛtti* for French translation; trans. S. Anacker, 'The Twenty Verses and their Commentary', in Anacker 1984; trans. T. Kochumuttom, 'A Treatise in Twenty Stanzas', in Kochumuttom 1982.(Along with the *Triṃśikākārikāvṛtti*, one of the foundational texts for Yogācāra theory.)

Vātsyāyana (5th century)

Vātsyāyana belonged to the Nyāya school of Indian philosophy, and his Nyāyabhāṣya is the first extant commentary on the Nyāyasūtra, the foundational text of that school. In it, he emphasized the distinctive epistemological and logical character of the topics he deemed appropriate for treatment by Nyāya philosophers. In so doing, he helped both to establish the authority of the Nyāya school in matters related to logical reasoning, and to demarcate the enterprise of the Nyāya school from that of the earlier, more traditional, soteriological approach of the Upaniṣads. His commentary on the Nyāyasūtra set the agenda for succeeding generations of Nyāya commentators and their Buddhist opponents. In particular, Vātsyāyana initiated arguments that were to become crucial in the Nyāya defence of its characteristic brand of realism.

Little is known about Vātsyāyana, who is also known as Pakṣilasvāmin. His precise dates remain a matter of scholarly interpretation of the relevant textual materials, most particularly the dating of the *Nyāyasūtra*, but placing him between 400 and 500 AD is a good working hypothesis. Vātsyāyana's chronological place in the enduring philosophical dialogue between the Nyāya and Buddhist philosophers is, however, much clearer. He directed many of his arguments against his Buddhist predecessor, Nāgārjuna, and, in turn, his work was criticized by the great Buddhist logician Dignāga. The dialogue continued with Uddyotakara, who sought to repair and develop Vātsyāyana's thought in the light of Dignāga's criticisms. In this fashion, the philosophical debate between the Nyāya and Buddhist philosophers continued until the eleventh century, with each side offering an ever more refined defence of its position; it culminated in the great philosophical wrangle between the Nyāya philosopher Udayana and his Buddhist opponent Jñānaśrīmitra.

At stake was the Nyāya defence of realism. Nyāya is distinctive among Indian schools of philosophy in its advocacy of a form of direct realism, in which the world is seen to be made up of everyday objects, such as pots and cows, amenable to both direct perception and to verbal expression. The possibility of forming correct judgments about the objects in the world (*prameya*) rests upon the efficacy of the four accredited instruments of knowledge (*pramāṇa*), listed in the *Nyāyasūtra* as perception, inference, comparison and verbal testimony (see Nyāya-Vaiśeṣika §6). In the *Nyāyabhāṣya*, Vātsyāyana attempted to counter Nāgārjuna's devastating critique of the very notion of a *pramāṇa*, a critique which had endangered the whole epistemological enterprise of the Nyāya school. He also defended, in the face of a developing Buddhist phenomenalism, the Nyāya view of the direct perception of objects. In so doing, he helped to clarify the relationship between perception and language.

Nāgārjuna had charged that the Nyāya dependence on the four *pramāṇas* was itself in need of substantiation. How can we be sure of the reliability of the *pramāṇas* themselves? Does our certitude come from invoking a further set of *pramāṇas*, taking the first step towards an infinite regress? In the *Nyāyasūtra* itself (2.1.19) we find a hint of the problem, when it is suggested rather cryptically that the *pramāṇas* are like lamp light. Since a lamp is self-illuminating, it was suggested that a *pramāṇa* could be self-validating. Vātsyāyana rejected such an interpretation. Not only does it fail to address Nāgārjuna's doubts about the *pramāṇas*, it also contradicts the basic Nyāya view that the *pramāṇas* alone, without any additional category of self-evidence, should be the source of knowledge. In his commentary on this *sūtra*, Vātsyāyana explains that the purpose of the lamplight analogy is to demonstrate that the *pramāṇa*-*prameya* distinction is neither rigid nor mutually exclusive. Since a lamp can fulfil two roles, both revealing other objects with its light and itself being an object of cognition, this demonstrates how one and the same object can function as both *pramāṇa* and *prameya*. Having resisted the idea that any set of *pramāṇas* should be considered axiomatic, Vātsyāyana attempts to show how the justification for any *pramāṇa* can come from the *pramāṇas* themselves. He points out that each *pramāṇa* is a generic term, encompassing different acts of knowing of the same type. Thus if one act of perception is validated by another act of perception, this should not be seen as a *pramāṇa* validating itself. Vātsyāyana's reply to Nāgārjuna may be viewed as somewhat pragmatic. Any individual use of a *pramāṇa* can itself be the object of another cognition. This, he says, is sufficient for the pursuit of everyday business as well as liberation (*mokṣa*), and does not lead to an infinite regress.

In dealing with the individual *pramāṇas*, Vātsyāyana's dispute with the Buddhist phenomenalists over where to draw the line between perception and inference was crucial to Nyāya's realist view of the world. In the

Nyāyasūtra (1.1.4), perception had been characterized as 'that which is not expressible' (*a-vyapadeśyam*). Vātsyāyana uses this *sūtra* to argue that, as with infants, the ability to perceive an object is different from the ability to name it. This distinction between the perception of an object and its linguistic characterization anticipated an important distinction later Nyāya philosophers made between qualified and nonqualified perception. Vātsyāyana, however, strongly opposed the Buddhist view, which sought to drive a wedge between perception and language by making judgments of the form 'this is a cow' inferential rather than perceptual. Nyāya asserted a close accord between language and perception with the argument that perception gives us direct access to substantial, enduring objects like cows and trees. In the course of his arguments for the direct perception of physical objects, Vātsyāyana develops the arguments given in the *Nyāyasūtra* (2.1.31-6) concerning the relationship between a whole and its parts. While accepting that we can never simultaneously perceive all the parts of a tree, Vātsyāyana rejects the assumption that we need to do so in order to see a tree as such. A tree is a unity which is more than a mere conglomeration of its component parts, and which resides in its entirety in the parts of the tree. Vātsyāyana argues that if we are to speak of 'trees' at all, we must maintain the distinction of a whole over and above its parts. Later Nyāya realists, especially Uddyotakara and Udayana, made effective use of this distinction.

There are frequent references to Vātsyāyana and his role in this long philosophical dispute.)

Vedānta

*Indian philosophical speculation burgeoned in texts called Upaniṣads (from 800 BC), where views about a true Self (*ātman*) in relation to Brahman, the supreme reality, the Absolute or God, are propounded and explored. Early Upaniṣads were appended to an even older sacred literature, the Veda ('Knowledge'), and became literally Vedānta, 'the Veda's last portion'. Classical systems of philosophy inspired by Upaniṣadic ideas also came to be known as Vedānta, as well as more recent spiritual thinking. Classical Vedānta is one of the great systems of Indian philosophy, extending almost two thousand years with hundreds of authors and several important subschools. In the modern period, Vedānta in the folk sense of spiritual thought deriving from Upaniṣads is a major cultural phenomenon.*

Understood broadly, Vedānta may even be said to be the philosophy of Hinduism, although in the classical period there are other schools (notably Mīmāṃsā) that purport to articulate right views and conduct for what may be called a Hindu community (the terms 'Hindu' and 'Hinduism' gained currency only after the Muslim invasion of the South Asian subcontinent, beginning rather late in classical times). Swami Vivekananda (1863-1902), the great popularizer of Hindu ideas to the West, spoke of Vedānta as an umbrella philosophy of a Divine revealed diversely in the world's religious traditions. Such inclusivism is an important theme in some classical Vedānta, but there are also virulent disputes about how Brahman should be conceived, in particular Brahman's relation to the individual.

In the twentieth century, philosophers such as Sarvepalli Radhakrishnan, K.C. Bhattacharyya and T.M.P. Mahadevan have articulated idealist worldviews largely inspired by classical and pre-classical Vedānta. The mystic philosopher Sri Aurobindo propounds a theism and evolutionary theory he calls Vedānta, and many others, including political leaders such as Gandhi and spiritual figures as well as academics, have developed or defended Vedāntic views.

1 Pre-classical Vedānta

The most abstract teaching of the earliest Upaniṣads centres on questions of theological metaphysics: what is the ultimate reality, what is its nature and relation to the world, and how can it be known? The ultimate reality is called Brahman, and all Vedānta, from the pre-classical to the modern, is Brahman-centred philosophy. Early Upaniṣads also include much psychological speculation, about a true self (*ātman*), at places declared identical with Brahman. Dimensions or layers of self-experience are identified, for example, a series of states of awareness in dream and sleep, and a series of bodies (*kośa*) ranging from the physical body to a vital 'sheath', then a mental sheath, then a 'supramental' sheath, and finally a most essential sheath said to be 'made of bliss'.

Early Upaniṣads are as much mystical treatises as philosophical texts. A mystical awareness of Brahman (*brahma-vidyā*) is the core teaching concerning human destiny, a 'supreme personal good' (*parama-puruṣārtha*). Upaniṣadic idealist speculation appears to be an attempt to explain the possibility of an exalted consciousness: Brahman as transcendent (timeless, spaceless) but also as world ground is somehow directly experienced as identical with the individual self. Even theistic passages, which suggest that Brahman is transcendent to the world and individuals as their Creator and Lord, teach the value of knowing Brahman directly through assiduous efforts of meditation and yoga (which literally means 'self-discipline').

The psychological thesis that self-awareness is nondual, that awareness is evident to itself without an intermediary or another awareness, is presented with an analogy to light: light is self-luminous; similarly, awareness is self-aware. This thesis is key to the classical Vedāntic subschool known as Advaita ('Nondualism') - as too is a causal doctrine, namely, that an effect is prefigured, or immanent, in its material cause, for example, a gold bracelet in gold (see §3). The Advaita Upaniṣadic reading stresses the sole reality of Brahman, who is nondualistically self-aware. Positions key to theistic subschools, opposed to the Advaita reading, are also adumbrated in various passages. Early Upaniṣads do not speak with a single voice.

However, views are expressed that span not only all the classical Vedāntic subschools but also the full extent of pre-classical, classical and even much modern Indian thought. For example, doctrines of karma and rebirth are veritably pan-Indian. Some Upaniṣadic teachings about moral virtues remain fairly constant through the later

civilization, although different emphases emerge in different religious and ascetic traditions. Social doctrines of caste are not prominent in the earliest Upaniṣads, but there are indications that a hereditary system of social privilege and responsibility was in the process of being formed.

Another pre-classical Vedāntic text is that portion of the *Mahābhārata* (the great Indian epic) known as the *Bhagavad Gītā(Song of God)*, which is probably the most popular religious work in the whole of Indian civilization. The *Bhagavad Gītā* echoes several Upaniṣads and develops Upaniṣadic themes and theses about the self as well as about Brahman. But whereas early Upaniṣads include many passages centred on ideas dear to classical Advaita Vedānta (and there are middle and late Upaniṣads that express only the Advaita point of view), the *Bhagavad Gītā* is to be aligned for the most part with the theistic classical subschools. Brahman is God, according to the *Bhagavad Gītā*, the Creator of the universe that God indwells. God is both transcendent to and immanent in this world (see God, Indian conceptions of §3). The *Bhagavad Gītā* upholds mystical awareness of Brahman - along with the yoga or discipline required for such awareness - as the solution to this-worldly ethical and political crises, a view echoed in modern times by Mahatma Gandhi and other nationalist leaders. In contrast to Upaniṣadic ideas about Brahman as beyond good and evil, in the Vedāntic theism of the *Bhagavad Gītā* and other texts, God upholds *dharma*, right conduct, and in special manifestations or *avatāras* (Kṛṣṇa, Rāma and so on) is born into the world to keep the social order on track.

In this way, by the end of the Upaniṣadic period (200 BC or thereabouts) Vedānta had begun to develop along two lines: Brahman - the Supreme Being by all counts - is conceived as a personal God, the Creator and Sustainer of the universe, manifesting as the several gods and goddesses and incarnate in *avatāras*; or, alternatively, Brahman is seen as an impersonal Ground of Being in the (idealist) sense of the entire phenomenal display of this universe viewed as a dream or illusory projection of a single Self. In all cases, the notion of liberation, that is, mystical knowledge or realization of Brahman (*brahma-vidyā*), is prominent, but the term is not understood in the same way by Advaita Vedāntins and theists. Advaitins come to hold that the self (*ātman*) of everyone is in reality nothing other than Brahman, and that in the mystical knowledge of Brahman there is known only the One, the sole true Existent, whose nature is strictly beyond determination by finite beings such as us; but that it is a homogeneous Being, Consciousness and Bliss is put forth as an idea to guide mystic pursuits. Vedāntic theists, in contrast, come to hold that the individual and God are meaningfully distinct. In the ‘highest knowledge’, the Supreme cannot be known in precisely the fashion that God knows God, for an individual knower is not strictly identical with the Creator, although God indwells everywhere, including, to be sure, the individual self. Advaita Vedāntins come to stress meditation and study of Upaniṣads to attain the *summum bonum*, while Vedāntic theists stress love and devotion to God.

2 The *Brahmasūtra*

Classical Indian philosophy is marked by argument and self-conscious defence of positions, as well as by an acute awareness of systematic interlock among the planks of a worldview or school. Distinct worldviews, represented in the several schools of classical philosophy, had emerged by the first few centuries AD. With exceptions (principally concerning Buddhist schools), each school has an early *Ur*- or root text that lays out positions comprehensively but also in abbreviated form - in *sūtras*, ‘threads’ or aphorisms that are compact and easy to memorize. Examples of basic texts are the *Mīmāṃsāsūtra*, defining the school of Mīmāṃsā, the *Nyāyasūtra*, spelling out Nyāya, and so on. The apparent root text of classical Vedānta is the *Brahmasūtra*. However, although the founders of the prominent Vedāntic subschools (Śaõkara, Bhāskara, Rāmānuja, Nimbārka, Madhva and Vallabhācārya) all write commentaries on the *Brahmasūtra* - each interpreting distinctively at least some of the terse and often vague or ambiguous *sūtras* - the Upaniṣads themselves, and not the *Brahmasūtra*, are the foundational Vedāntic texts. This is unlike the situation with, for example, Nyāya, where the *Nyāyasūtra* is veritably the foundational text. The *Brahmasūtra* should be regarded, then, as the text that first establishes a Vedāntic system, but not as the definitive statement of Vedāntic positions. The fact that there are diverse Vedāntic subschools attests to the diversity of Upaniṣadic teachings and to the vibrancy of Upaniṣadic traditions of study and learning well into classical times.

The *Brahmasūtra* is also known as the *Śārīrakamīmāṃsāsūtra (Aphorisms of (Scriptural) Exegesis Concerning the Embodied)*. The *Brahmasūtra* presupposes the *Mīmāṃsāsūtra (Aphorisms of (Scriptural) Exegesis (Proper))* - that is, an interpretation of the Veda including, according to classical Exegetes (Mīmāṃsakas), Vedānta’s Upaniṣads as well as the Vedas proper. Classical Vedānta is sometimes referred to as Uttara Mīmāṃsā, Later Exegesis, being

focused on the later portions of scripture (Upaniṣads) and contrasting but also continuous with Pūrva Mīmāṃsā, Prior Exegesis, which is focused on the earlier portions of scripture and is the school of Mīmāṃsāproper. A principal task the *Brahmasūtra* sets for itself is to differentiate Vedānta from Mīmāṃsā. This it does by declaring Brahman to be the object of Upaniṣadic statements, whose point is to provide insight and lead to mystical knowledge, as opposed to the Mīmāṃsāunderstanding of scripture as a series of injunctions on right ritual, right practice and in general the right way to live. The *Brahmasūtra* adopts Mīmāṃsā's epistemology of scripture as self-certifying and authoritative within its own sphere (see Knowledge, Indian views of §3; Mīmāṃsā). But it specifies that that sphere is distinct in the case of the Upaniṣads; it is, namely, Brahman and knowledge of Brahman. The rites and actions prescribed by scripture for the embodied soul, the human agent, according to Exegetes, are, according to Vedāntins, nullified by the superior path of knowledge, whereby the embodied will come to know Brahman and be liberated from rebirth and death and future embodiment.

The *Brahmasūtra* has less subtle quarrels with other classical schools, although regarding Sāōkhya, scriptural interpretation remains the major issue. Early Upaniṣads do, in fact, at places resonate with Sāōkhya's understanding of nature or *prakṛti* as prefiguring within her unmanifest form all worldly manifestations. Moreover, Sāōkhya's hierarchical psychology of an embodied soul and its instruments or faculties, from reason to sense organs and organs of action, is rather clearly an Upaniṣadic teaching (see Sāōkhya). The *Brahmasūtra* is intent on integrating these views within a Brahman-centred philosophy, and disputes the contention that Sāōkhya is expressed in the Upaniṣads. But the *Brahmasūtra* also disputes Sāōkhya on metaphysical and other nonscriptural grounds. And Buddhist schools, Nyāya, Vaiśeṣika, Jainas and others are engaged and refuted on a wide range of philosophical issues.

For example, against the Vaiśeṣika notion of inherence (*samavāya*) as ontic glue binding a property to a property-possessor, the *Brahmasūtra* alleges that an infinite series of relators would be required to bind the inherence itself to the property and to the property-possessor. In this way, the notion is shown to be bankrupt. Against a Buddhist understanding of awareness as neither occurring in a self nor revealing external states of affairs, the *Brahmasūtra* alleges that the evidence of perception is to the contrary. The Jaina view that the soul has size is opposed on the grounds of untoward ramifications with regard to liberation. Bādarāyaṇa, the person (otherwise unknown) to whom the *Brahmasūtra* is traditionally ascribed, appears thoroughly knowledgeable about the philosophical landscape of his time (probably the first or second century AD), and the *Brahmasūtra* suggests a similar development of argument as is evinced in other early *sūtra* texts of the philosophical schools.

3 Issues among the subschools

No *Brahmasūtra* commentary has come down us that is earlier than Śaōkara's (early eighth century), but we know that there were earlier commentaries because Śaōkara and others whose works are extant mention a few. After Śaōkara, the great Advaitin, there are commentaries by Bhāskara (*c.*750), Rāmānuja (11th century), Nimbārka (*c.*1250), Madhva (1238?-1317?) and Vallabhācārya (1479-1531), authors who establish subschools rival to Advaita. Other, mostly later (original), commentaries were written as well, but these philosophers are the founders of the major classical subschools. Śaōkara and most of the others have followers who write subcommentaries, and within Advaita a couple of these (by Padmapāda, *c.*725, and Vācaspati Miśra, *c.*950) carve out distinct interpretations that are important even from a distant perspective contemplating classical Indian philosophy as a whole. The writings of classical Vedāntins are not confined to *Brahmasūtra* commentaries and subcommentaries; there are numerous noncommentarial treatises, as well as commentaries written on various Upaniṣads and the *Bhagavad Gītā*.

In these works, the *Brahmasūtra*'s attacks on competing worldviews are extended and refined, with some shift of focus as various non-Vedāntic philosophies become prominent or decline. But increasingly - and as early as Bhāskara - internecine disputes are aired, and by the era of Madhva come to dominate Vedāntic argument. And although it would be an error to ignore differences among non-Advaitic subschools, it is Advaita that the other subschools are keen to combat. With Madhva and his followers, not only is opposition to Advaita vehement, but also an alliance with Nyāya, a pluralist worldview with its own long history and literature, has to be counted as important as any Vedāntic heritage. This contrasts sharply with the polemics of the Advaitin Śrīharṣa (*c.*1150), who devotes enormous energy to refuting Nyāya, dismantling that realist and pluralist philosophy's every position down to apparent minutiae. Thus the nature of Vedāntic unity becomes problematic, and in fact scholars rarely

refer to classical philosophers merely by a 'Vedānta' tag, but at least differentiate Advaitins from the rest. The key issue that divides Advaita from its Vedāntic opponents, and that (loosely) unites the opponents as well, is one that, as noted above (§1), flows out of the Upaniṣads themselves and the *Bhagavad Gītā*: is Brahman the impersonal homogeneous Absolute of Advaita, or the God of the rival camps?

Other issues are tied closely to disputes about Brahman, in particular, controversies about the nature of the individual (*jīva*) in relation to Brahman. In fact, the most commonly employed designations of Vedāntic subschools derive from stances taken on this issue: Advaita (Nondualism: Brahman and the individual - *qua* being conscious or being a self - are identical; otherwise individuality is illusion), Bhedābheda (the Distinctness in Nondistinctness view of Bhāskara and others: Brahman and the individual are in at least one way distinct realities and in another nondistinct), Viśiṣṭādvaita (the Qualified Nondualism view of Rāmānuja and followers: both Brahman and the individual are realities and also identical in a qualified sense), Dvaita (the Dualism view of Madhva and company: Brahman and the individual are fundamentally distinct realities), and so on.

The relation of Brahman and the individual was not considered simply a matter of abstract metaphysics; the soundness of practical disciplines, indeed, of whole ways of life, was viewed as hinging on it. Theistic Vedāntins upheld - and today Hindu theists continue to advocate - practices known as *bhakti*, 'love' or 'devotion', as the way to a mystical *summum bonum* sometimes symbolized as adulterous love-making with God. In contrast, Advaitins advocate more ascetic paths, along with intellectual pursuits - in particular, Upaniṣadic study. And the *summum bonum* is conceived as realization of Brahman where one nondualistically (and timelessly, and so on) knows only oneself.

Exegetical issues dominate the intra-Vedānta crossfire. Advaitins, sensing a tension between Upaniṣads theistic statements and their view of Brahman's transcendence and unitary consciousness, develop exegetical strategies to reinterpret troublesome passages. Foremost among these is a view of scripture as like a wise and patient guru tailoring his teaching to his audience's capacities. Thus theistic views, and *bhakti* practices as well, are regarded as helpful for those incapable of appreciating the highest Upaniṣadic teaching, the utter truth, namely, that there is a single, undifferentiated self. (Some Advaitins make greater concessions to theism, holding that God is the inevitable conception of the Absolute from the finite human point of view. This position is often rehearsed among academic Neo-Vedāntins; see §4.)

Theistic Vedāntins, for their part, insist on a more literal reading of the Upaniṣads. Some also argue that all conveyance of meaning presupposes things as distinct. Moreover, the very act of comprehension of scriptural statements presupposes the reality of an individual cognizer. Advaitins are pushed by some of these points to assert the importance of nonliteral language, and struggle to formulate an appropriate theory of metaphor. They also admit that even a scripturally based understanding belongs to the province of illusion (*māyā*).

Concerning psychological and epistemological stances, there is less disagreement. Vedāntic theists tend to endorse the Advaita view of self-awareness as irreflexive and the Mīmāṃsāepistemology of self-certification (see Epistemology, Indian schools of §3). They also embrace the Upaniṣadic monism of Brahman as all-containing. But they refuse to go the subjectivist route in interpreting this doctrine, and dispute the Advaita view of worldly, finite things as an illusory projection of a single self. Instead, they see the unity of Brahman as a doctrine of material causality. With regard to the 'stuff' of the universe, a kind of Advaita is right: the world is the body of God. Even Madhva, who often seems intent on holding that in no way are God and individuals anything but distinct, says that God's body is the universe. According to Rāmānuja and other theists less radical than Madhva, Brahman has two natures: God as God is in God's self, which is God's necessary and essential nature, and God as God self-manifests in the world, as finite things that are real but contingent and inessential (see God, Indian conceptions of §3).

4 Neo-Vedānta

In modern India, the intellectual landscape has changed dramatically from classical times, reflecting science and influenced by Western thought. Vedānta, however, has proved surprisingly resilient, and not just within religious traditions but within universities as well. Colleges and universities were founded in India during the nineteenth century and academia has expanded enormously since then. Sanskrit, the intellectual language of the ancient and classical civilizations, has been replaced by regional vernaculars or English in most educational settings, and in

higher education English predominates. Philosophy is taught by professionals who are, by and large, at least as knowledgeable about the history of Western philosophy as about ancient or classical Indian thought. Nevertheless, what has come to be called Neo-Vedānta is a major intellectual movement on the campuses. There is also a Neo-Vedānta that is more a folk or religious phenomenon. Both types of Neo-Vedānta have complex roots, reflecting in part contemporary Hinduism and healthy traditions of mysticism, in part survival of classical modes of learning, in part Western idealist philosophy and in part deepened scholarly appreciation of classical Indian thought.

Concerning the folk phenomenon, it is probable that all Indian worldviews propounding a mystic goal grew up within traditions marked by the prominence of a spiritual teacher or guru; similar traditions continue today. Within contemporary Hinduism, each guru fashions a heritage from a wealth of prior Indian religious literature (the *Bhagavad Gītā*, Upaniṣads, Purāṇas, stories of the living enlightened, and so on) and, in some cases, from literature of other traditions as well. The best-known spiritual figures, eminently articulate gurus with national and international audiences, such as Swami Vivekananda (1863-1902) and Sri Aurobindo (1872-1950), are folk Vedāntins in the sense that, without allegiance to a school of classical thought, they draw on the *Bhagavad Gītā* and Upaniṣads and works influenced by classical Vedāntic conceptions. Both of these two great men learned Sanskrit, but, as has become increasingly common, both write in English. Vivekananda defends Vedānta as the plastic philosophy of Hinduism (see Ramakrishna movement); Aurobindo articulates a Brahman-centred worldview which he says is attuned to science but provides a deep explanation of which science, he argues, is incapable.

With regard to the nineteenth and early twentieth centuries, there would be little point in trying to differentiate folk and academic Neo-Vedānta. Although not professional academic teachers of philosophy (a rare thing in India, and indeed the West, at that time), Vivekananda and Aurobindo were well schooled in Western modes of thought. But it is with such broadly important cultural figures as Raja Rammohun Roy (1772-1833), sometimes referred to as the father of modern India, that Vivekananda and Aurobindo have affinity, not with any contemporary professor. Indeed, although Roy was no guru or spiritual leader, he may be taken as the first to articulate in the religious arena a synthesis of Western and Indian views. Among diverse accomplishments, he translated the New Testament into Bengali after learning Greek to read the original text. In ethics, he championed Christianity, urging that Hindus could and should embrace Christian moral teachings without relinquishing their own Vedāntic theological beliefs. In 1828, he founded the Brahmo Samaj (see Brahmo Samaj), a ‘church’ dedicated to ‘the worship and adoration of the Eternal, Unsearchable and Immutable Being, who is the Author and Preserver of the universe’ (Roy 1906, vol. 1: 216).

But although having wide influence, Roy, Vivekananda, Aurobindo and other important cultural figures were and are not professional philosophers. Academic Neo-Vedāntins differ markedly from nonprofessionals in ways reflective of a university setting. Sarvepalli Radhakrishnan (1888-1975), the most distinguished to date of these Neo-Vedāntins - President of India (1962-7), Spaulding Professor at Oxford (1936-9), Vice-Chancellor of Benares Hindu University (1939-48), Chancellor of Delhi University (1953-62) and teacher of philosophy at three other Indian institutions - used books and papers on classical systems, heavily peppered with apt comparisons to Western thought, to develop his own views. These are stated forthrightly in *An Idealist View of Life* (1929), but with Radhakrishnan’s typically careful scholarship and much attention to forerunners, chiefly Western idealists, but also classical Vedāntins. K.C. Bhattacharyya (1875-1949), professor of philosophy at the University of Calcutta and the teacher of many of the most important philosophers of the next generation, supports several Advaita-like views with tightly constructed arguments and insights expressed in austere, difficult prose. T.M.P. Mahadevan (1911-92), longtime professor of philosophy at the University of Madras, authored literally hundreds of papers and a dozen or so books, principally in exposition of the views of classical Advaitins - often defending Advaita in contemporary terms. More conservative than Radhakrishnan or Bhattacharyya, Mahadevan built bridges to folk traditions by discussing such popular saints as Ramakrishna and Ramana Maharshi. The Neo-Vedānta that these three present is a deep-set movement among philosophy professionals. Several others of similar persuasions deserve mentioning, but this is not the place for a long list.

Venn, John (1834-1923)

John Venn was a British symbolic logician and methodologist of science. He is known for having invented the method of Venn diagrams for judging the validity of categorical syllogisms and for advocating the 'compartmental' conception of categorical propositions which they display. He strongly defended Boole's algebraic methods in logic by giving them clear logical meanings. He provided the first systematic formulation of the frequency theory of probability, and he showed the uncertainties inherent in the use of J.S. Mill's inductive methods.

Venn was born in Drypool, Hull. A member of Gonville and Caius College, he graduated from Cambridge in 1857. He became college lecturer in moral science at Cambridge in 1862 and worked for thirty years on problems in symbolic logic and the methodology of science. He turned later to biographical and antiquarian topics related to his family and college, of which he was President from 1903 until his death.

Venn is best known as the creator of the method of Venn diagrams for testing categorical syllogisms (see Logic machines and diagrams §3). Two features of Venn's method are especially important. The first is that it is not limited to three classes. He was, in fact, remarkably adept at using Venn diagrams to test arguments involving four or even five class terms. The second feature is that these diagrams graphically represent Venn's analysis of categorical propositions. Venn detected three types of analysis of categorical propositions in the logical tradition: the predicational view ('all *X* are *Y*'), the class inclusional and exclusional view ('the class of *X*s is included in the class of *Y*s'), and the compartmental or existential view ('the class of things that are *X* and non-*Y* is empty'). Venn adopted the latter conception, and this is precisely what is shown by Venn diagrams. His use of the compartmental view was based on its convenience rather than its ultimate truth. While a 'complete Theory of Logic' would require that one give the '*true* account', his own goal was to find the most convenient logical methods.

Venn's most important work, *Symbolic Logic* (1881), was a spirited defence of Boole's algebraic techniques for logic in the face of the modifications which Jevons, Peirce and others had made in the preceding decades; (see Boole, G.; Boolean algebra). Of Boole's use of inverse operations - subtraction as the inverse of class union and division as the inverse of class intersection - the latter caused most controversy. Boole had claimed that the use of division gave rise to uninterpretable formulas, but thought this acceptable as long as the end results of logical calculations were interpretable. Jevons and others, though, claimed that such a mysterious sign should be dropped from logic entirely. Venn strongly defended its retention, holding that by dropping it, 'nearly everything which is most characteristic and attractive in the system is thrown away' (1881: xxviii).

Venn's project, then, was to reinstate Boole's original techniques by allowing division. Contrary to Boole, though, he believed that the formulas which resulted from using division could be given clear logical meanings. On his view, 'x/y' stands for any class which is such that the intersection of x/y and *y* is identical with *x*. This will obtain only when all *x* is *y* (that is, $x = xy$). Furthermore, there will usually be many classes which have this characteristic. Thus 'x/y' stands for a one-many partial function of *x* and *y*. This explanation allowed Venn to give a logical explanation of many of the otherwise puzzling formulas in Boole's logic.

Venn was also concerned with the logic of science. In *The Logic of Chance* (1866), he rejected the commonly held view that probability theory deals with degrees ('gradations') of belief. He presented, instead, the first systematic formulation of the frequency theory of probability, in which probability assertions are empirical assertions about the frequency with which types of events will happen in the long run. Venn realized that the relationship between probability in this sense and other uses of the word 'probability' remained puzzling. The probability of single events seems undefined, as is the probability that an empirical frequency may give to a hypothesis concerning a long-run frequency (see Probability theory and epistemology).

Venn presented a systematic analysis of scientific method in *The Principles of Empirical or Inductive Logic* (1889). While heavily influenced by Mill, he found Mill's inductive methods to be uncertain (see Mill, J.S. §5). Applying Mill's methods to scientific problems requires far more knowledge than scientists normally have. This criticism reflects the strongly empiricist, even sceptical, mode of thought which characterized Venn's work.

Vernia, Nicoletto (d. 1499)

Nicoletto Vernia was a celebrated Aristotelian philosopher during the second half of the fifteenth century. His acquaintances included such personalities as Ermolao Barbaro, Giovanni Pico della Mirandola, Pietro Pomponazzi and Agostino Nifo. His special interests were in natural philosophy and psychology, but he also revealed interests in logic. Although usually characterized as a rigid Averroist, he moved from a clear commitment to Averroes as the true interpreter of Aristotle to a preference for the Greek commentators, especially Themistius and Simplicius. Nonetheless, throughout his career he also maintained a noteworthy interest in Albert the Great. After first attempting to conciliate Albert with Averroes as much as possible, he later attempted to conciliate Albert with the Greek commentators. He was one of the first Renaissance Aristotelians to use the commentary on Aristotle's On the Soul that is attributed to Simplicius, and also to cite Plato, Plotinus and their translator and expositor, Marsilio Ficino.

1 Life and works

Nicoletto Vernia, a native of Chieti, studied at Padua with Cajetan of Thiene (Gaetano da Thiene) and Paul of Pergola. Around 1467-8 he spent a year at Pavia studying the *Calculationes* of Richard Swineshead (see Oxford Calculators), most likely with Giovanni Marliani. After his return to Padua he took the chair of Cajetan of Thiene in 1468. In his early writings he consistently states that Averroes (see Ibn Rushd) gives the true interpretation of Aristotle. What is striking is that he regularly attempts to reconcile Averroes and Albert the Great. In 1489 Pietro Barozzi, Bishop of Padua, issued a decree which forbade lecturing on the unity of the intellect according to Averroes and accused Vernia of having filled Italy with this error. Although Vernia submitted to the decree, it appears from the marginal annotations dating from 1487 and 1489 in his copies of Aristotle and John of Jandun that he already had doubts about the philosophical viability of the doctrine of the unity of the intellect, and had begun to study the Greek commentators on Aristotle, especially Alexander of Aphrodisias, Themistius and Simplicius (see Aristotle Commentators). That interest in the Commentators, which may reflect the influence of Ermolao Barbaro and Giovanni Pico della Mirandola, is obvious in his posthumously published questions against the 'perverse doctrine' of the unity of the intellect (*Contra perversam Averrois opinionem*) (dated 1492, but published posthumously in 1504). In that work, Vernia uses Marsilio Ficino and reconciles Albert the Great with Themistius and Simplicius. Basing himself in particular on Simplicius, he proposes that Plato and Aristotle hold the same doctrine, and differ only in words. Throughout his life Vernia seems to have had an irascible side that on occasion led to the expression of hostility towards others.

2 Logical issues

Vernia was one of the Renaissance Aristotelians who discussed the nature of a so-called most powerful, or absolute, demonstration (*demonstratio potissima*) and the sources of its premises. Such a demonstration was considered to provide perfect causal knowledge of some effect. Vernia explains that after resolution of the information provided by sense experience into a preliminary and imperfect universal knowledge there is a movement of the intellect (*negotiatio intellectus*) that seeks the cause of the effect being studied and that establishes the premises that produce the desired demonstrative or apodictic knowledge (see Zabarella, J. §5).

In his treatise on the division of the sciences (1482a), Vernia states that while the dialectical syllogism concerns the probable, the probable includes necessary things as well as contingent things. Even natural philosophers, mathematicians and metaphysicians can be considered to study the probable. In his question on whether medicine is more excellent than civil law (1482b), he maintains that medicine, subalternated to natural philosophy, demonstrates and knows that it is doing so, whereas law rests on the authority of the learned and is subalternated to politics, a science lower than natural philosophy. At best law achieves the dialectical habit of mind that prepares for demonstration.

3 Natural philosophy

In a question on the subject of natural philosophy (1480), Vernia pays Thomas Aquinas great respect but argues against the view of the Angelic Doctor that mobile being (*ens mobile*), which might include angels, is the subject of natural philosophy. He takes the true interpretation of Aristotle to be that of Averroes, whom he presents as

holding mobile body (*corpus mobile*) to be the subject of natural science (*scientia naturalis*). He attacked such earlier writers as John Canonicus and Antonius Andreas for not speaking in a natural fashion when they appeal to the motion of angels in order to discredit Aristotle's natural philosophy (see Cajetan §3).

In his early *De gravibus et levibus (On Things Heavy and Light)* (before 1476), Vernia examines the problem whether heavy and light inanimate things move locally by themselves or by virtue of something else, once the factor preventing (*prohibens*) motion is removed. He argues that Averroes' position on the question is the correct reading of Aristotle. He emphatically rejects as 'theologizers' (*theologizantes*) those who maintain that the quality of heaviness (*gravitas*) moves objects as a primary and principal agent, arguing from transubstantiation in the Eucharist that the heaviness of the consecrated host moves downwards even though that heaviness is separated from the substance of the bread. In like fashion, he rejects all appeals to God's absolute power (*potentia absoluta*) when discussing questions of natural philosophy.

A particular target of his attack is the position that explains the motion of a projectile not by air pushing behind it but rather by an impetus (*impetus*) imparted to the projectile. Vernia considers this view to deviate from Aristotle and truth. In contrast, he attempts to reconcile Averroes and Albert the Great on the topic, maintaining that when two such excellent philosophers agree, no one of sound mind should doubt that this is the mind of Aristotle.

4 Psychology

In an early work that he calls the *Question on the Unity of the Intellect* but never published, Vernia discusses whether the human soul is eternal and one in number for all humans or whether it is united in existence to the human body as a true substantial form. His announced purpose is threefold: (1) to set forth the doctrine of Plato; (2) to present what Aristotle held according to his most famous Greek and Arab commentators; and (3) to examine the Latin commentators and the truth of the Catholic faith. His brief summary of Plato's doctrine of the soul is culled from Albert the Great and Calcidius' translation of *Timaeus* 41 A-D (see Plato §§4, 13). In the second part, he presents and defends Averroes' doctrine of the unity of the intellect (namely that all human beings share one intellect) as the true interpretation of Aristotle. In the third part he attacks Albert, Aquinas and Duns Scotus for teaching that there are many intellective souls which are created by God, since Aristotle did not admit creation. To attribute to Aristotle the thesis of creation would be to hold that he maintained an infinite number of intellective souls infused in an infinite number of bodies, but this is false. Moreover, he rejects the accounts of individuation held by Aquinas and Duns Scotus, namely individuation through the soul's relation to a body and individuation through 'thisness' (*haecceitas*). He also characterizes Aquinas' and Duns Scotus' insistence that the human being cannot have a direct vision of God during this life as false according to Aristotle.

Subsequently Vernia changed his mind completely and wrote questions, dated 1492 but published posthumously in 1504, against Averroes' doctrine of the unity of the intellect. In the first part he again relies on Albert the Great when presenting Plato. But he now quotes Plato's *Timaeus* 41 A-D in the translation of Marsilio Ficino. In the second part, he rejects Averroes' doctrine of the unity of the intellect, basing himself on what he takes to be the common doctrine of the Greek commentators, namely Theophrastus, Alexander of Aphrodisias, Themistius and Simplicius. His misreading of Alexander as a proponent of the immortality of the soul is also to be found in Giovanni Pico della Mirandola, and was later strenuously attacked by his former student, Agostino Nifo.

Vernia maintained that Aristotle held the intellective soul to be multiplied according to the number of bodies. He even claims, citing Simplicius, that any disagreement between Plato and Aristotle is only verbal, since both maintain that the intellective soul was created by God from all eternity and therefore pre-exists the body. Only subsequently is the soul infused into a body as its substantial form; at death it will return to the dwelling place of a star. Vernia attributes to Aristotle Plato's doctrine that knowledge is recollection from a prior existence. Vernia's psychological thought thus evolved from a strict adherence to Averroes to a commitment to the Greek Commentators, and to an interest in Plato and Plotinus as known through the translations and comments of Ficino.

EDWARD P. MAHONEY

List of works

Vernia, N. (before 1476) *Quaestio de gravibus et levibus (Question on Things Heavy and Light)*, in Cajetan of

Thiene, *Expositio in libros Aristotelis De coelo et mundo*, ed. N. Vernia, Padua: Magister Bonus.(Vernia considers the question whether inanimate objects move locally by themselves or due to something else to be the most difficult question in physics. An impetus given to air and not to the body is the cause of the body's motion.)

Vernia, N. (1480 or earlier) *Utrum anima intellectiva humano corpore unita tanquam vera forma substantialis dans ei esse specificum substantiale eterna atque unica sit in omnibus hominibus (Whether the Intellective Soul is United to the Human Body as a True Substantial Form or is Eternal and One in All Humans)*.(Vernia's *Question on the Unity of the Intellect*; available in a single manuscript held at the Biblioteca Nazionale San Marco (Marciana) in Venice (see Pagallo 1964). Averroes' doctrine of the unity of the intellect is presented as the true mind of Aristotle. Albert the Great, Aquinas and Duns Scotus are criticized for attempting to prove that each human being has an individual intellective soul.)

Vernia, N. (1480) *Quaestio an ens mobile sit totius naturalis philosophiae subiectum (Question whether Mobile Being is the Subject of All Natural Philosophy)*, in Giles of Rome and Marsilius of Inghen, commentaries on Aristotle's *On Generation and Corruption*, ed. N. Vernia, Padua: Joannes Herbort.(Completed at Padua in 1480. Averroes' position, that mobile body is the subject of natural science, is the true interpretation of Aristotle.)

Vernia, N. (1482 or earlier) *Utrum sint ponendae rationes seminales in materia respectu rerum quae ex ipsa generantur (Whether Seminal Reasons are to be Posited in Matter with Respect to the Things Generated from It)*, in E.P. Mahoney, 'Nicoletto Vernia's Question on Seminal Reasons', *Franciscan Studies* 38 (1978): 299-309.(Vernia presents and then rebuts twenty arguments against seminal reasons.)

Vernia, N. (1482a) *De divisione philosophiae (On the Division of Philosophy)*, in W. Burley, *Expositio in libros octo de physico auditu*, ed. N. Vernia, Venice: Joannes Herbort, 1482.(Vernia shows special interest in Themistius in the translation of Ermolao Barbaro.)

Vernia, N. (1482b) *Quaestio an medicina nobilior atque praestantior sit iure civili (Question whether Medicine is More Noble and Distinguished than Civil Law)*, in E. Garin (ed.) *La disputa delle arti nel Quattrocento*, Florence: Vallecchi, 1947, 111-23.(Completed in 1482 and first published with the *De divisione philosophiae*. Medicine as theory or science consciously uses demonstrative reasoning and is subalternated to natural philosophy; law rests on authority and is subalternated to politics. Medicine is therefore superior.)

Vernia, N. (1492) *Contra perversam Averrois opinionem de unitate intellectus et de animae felicitate quaestiones divinae (Divine Questions Against the Perverse Opinion of Averroes on the Unity of the Intellect and the Felicity of the Soul)*, in Albert of Saxony, *Acutissimae quaestiones super libros de physica auscultatione*, Venice: Alexander Calcedonius and Jacobus Pentius, 1504. (Vernia now takes Averroes to have erred regarding Aristotle on the soul and intellect. The Greek commentators disagree with Averroes on the unity of the intellect. Philosophical arguments can be given for the creation of individual souls by God. Plato and Aristotle can be reconciled.)

Vico, Giambattista (1668-1744)

Vico lived in a period in which the successes of the natural sciences were frequently attributed to the Cartesian method of a priori demonstration. His own first interest, however, was in the cultivation of the humanist values of wisdom and prudence, to which this method was irrelevant. Initially, therefore, he sought a methodology for these values in the techniques of persuasion and argument used in political and legal oratory. But he soon came to believe that the Cartesian method was too limited to explain even the advances in the natural sciences and developed an alternative constructivist theory of knowledge by which to establish the degree of certainty of the different sciences. Wisdom and prudence, however, came low on this scale.

Through certain historical studies in law, he became convinced that, although there were no eternal and universal standards underlying law at all times and places, the law appropriate to any specific historical age was dependent upon an underlying developmental pattern of social consciousness and institutions common to all nations except the Jews after the Fall. His New Science (1725, 1730 and 1744) was a highly original attempt to establish this pattern, originating in a primeval mythic consciousness and concluding in a fully rational, but ultimately corrupt, consciousness. He believed that knowledge of the pattern would enable us to interpret a wide range of historical evidence to provide continuous and coherent accounts of the histories of all actual gentile nations. The primacy of consciousness in the pattern led him to claim that there must be a necessary sequence of ideas upon which institutions rested, which would provide the key to the historical interpretation of meaning in all the different gentile languages. He supported this conception by extensive comparative anthropological, linguistic and historical enquiries, resulting most famously in his interpretation of the Homeric poems. He also advanced a more developed account of his earlier theory of knowledge, in which the work of philosopher and historian were mutually necessary, to show how this conception of 'scientific history' was to be achieved.

Vico believed that the knowledge that wisdom and prudence vary in different historical ages in accordance with an underlying pattern could provide us with a higher insight into those of our own age and enable us to avoid a collapse into barbarism which, in an over rational age in which religious belief must decline, was more or less inevitable. Unfortunately, the metaphysical status of his pattern rendered this impossible. Much of his thought was expressed in a context of theological assumptions which conflict with important aspects of his work. This has given rise to continuous controversy over his personal and theoretical commitment to these assumptions. Despite this, however, his conceptions of the historical development of societies, of the relation between ideas and institutions, of social anthropology, comparative linguistics and of the philosophical and methodological aspects of historical enquiry in general, remain profoundly fruitful.

1 Life

Vico was born in Naples. His erratic early education included grammar, the Latin classics and philosophy. In 1684 he began to study for a practising career in law but he abandoned this in 1686 when he became tutor to the children of a wealthy family at Vatolla near Salerno. The years 1686-95 represent his only prolonged absence from Naples. In his *Autobiography* (1725, 1728, 1731) this is presented as a period of isolation from the lively intellectual life of Naples whereas, in fact, he remained in contact with it through membership of certain private societies and salons which had arisen to counteract the conservative influence of the Church and university. Through an intensive, self-directed course of study in the excellent library at Vatolla, he became acquainted with the thought of Plato and the Neoplatonists, the classical atomists such as Democritus and Lucretius, physicists such as Galileo and Gassendi, English thinkers such as Francis Bacon, Hobbes, Locke and Boyle and the rationalists, Descartes, Malebranche, Spinoza and Leibniz. By the end of this period he had acquired an encyclopedic, if idiosyncratic, understanding of the worlds of ancient and modern learning. The activities of the Inquisition make it difficult to be certain of his religious sentiments. Many of his friends were suspected of being atheists and it is sometimes thought, on the evidence of a Lucretian poem written in 1692, that he may have been an atheist at this time.

In 1694 he took his doctorate in law at Salerno and in 1699 he was appointed to the poorly paid Chair of Rhetoric at the University of Naples. Married in the same year, he subsequently had eight children and was constantly beset with financial problems which forced him to augment his income by the composition of official orations and histories. In 1723 he failed to gain the prestigious Chair of Civil Law. Abandoning hope of personal advancement,

he turned to the construction of the philosophy for which he is most famous, developing it progressively in the various versions of his *New Science* (1725 onwards). Much of our knowledge of his intense intellectual life is derived from the first and second parts of his *Autobiography*, written soon after the production of the first and second editions of the *New Science*. A third part, going up to his death, was later added by the Marquis of Villarosa. He remained a leading figure in Naples for the rest of his life, retiring from his Chair only three years before his death.

2 Early thought

Vico's primary aim was to show how philosophy could contribute to an understanding of the nature of wisdom and prudence in all their manifestations, personal, civil and political. This is evident from his earliest thought, expressed in *Six Inaugural Orations* given between 1699 and 1707, in which he argued that wisdom and prudence could be understood only through a study of the entire world of learning, human and divine. To justify the possibility of success he drew upon a Neoplatonic conception of the human mind as the image of God (see Neoplatonism). Just as God knows the world of his creation because he is active throughout that world, mind is the active incorporeal component in the cognitive, emotional and sensitive abilities required for the acquisition of knowledge. He supported the theological assumptions of this position by a series of Cartesian arguments: the *Cogito* and the causal and ontological proofs of God's existence (see Descartes, R. §§5, 6). But his conclusion, that we have been given all that the discovery of truth and virtue requires, rendered problematic why success should prove so elusive. In the sixth of his *Six Inaugural Orations* he therefore introduced a historical theory, drawn from the Bible, emphasizing our moral and intellectual corruption after the Fall. Dispersed throughout the world, the gentile nations have lost the languages, beliefs and inclinations necessary to reach the truth. What is needed, therefore, is a study of the world of human learning, ancient and modern, in order to establish the correct method to regain it. This is to be achieved by the development of wisdom, eloquence and prudence through an educational programme which respects a natural order of psychological development.

The metaphysical theory of mind played an important part in Vico's next two works. The first, *On the Study Methods of Our Time* (1709), clearly influenced by Francis Bacon, was an ambitious attempt to carry out the programme of the sixth of his *Six Inaugural Orations*. Vico's conclusion is that while there have been major advances in modern geometry, mechanics and physics, not all of these have the certainty claimed for them. They have, however, been influential in a loss of interest in the methods of education required for the successful conduct of social and political life because their advance has mistakenly been attributed to the Cartesian demonstrative method (see Descartes, R.). But the only field of knowledge in which demonstration can produce certainty is geometry, the elements of which are human constructions. This is the first indication of Vico's constructivist theory of knowledge: that we can know fully only what we have made (see Constructivism). Accordingly, although geometrical truths are required for the construction of physical theory, physics cannot achieve similar certainty because of its indispensable need for empirical experiment. At best it can claim verisimilitude. Demonstration is even less appropriate for the wisdom and prudence required in social and political life, because of the ineliminable influence of choice and chance. What is required here is a method for the development of sound judgment in human affairs. This existed in the classical art of topics, which was a body of categories and argumentative procedures used by lawyers to reach judgments in matters of fact and right in everyday life. But since this art is beyond the reach of the masses, who are ruled more by emotion than judgment, politicians must also master the ancient art of eloquence so that they can persuade the masses to adopt the practices recommended by the judgments reached through topics.

3 Early thought (continued)

Vico's next work, *On the Most Ancient Wisdom of the Italians Unearthed from the Origins of the Latin Language* (1710), was intended as a three-part treatise on metaphysics, physics and ethics. Only the first part was completed and published but the constructivist elements in his thought were now made quite explicit. The metaphysical thesis remains in the conception of a God who knows the metaphysical Forms on which the physical world is modelled because he creates them. We, made in the image of God, can also know what we create. This is expressed in Vico's *verum-factum* theory: the true is convertible with the made. The true is thus relativized to the mode of mental construction. To this, however, Vico now added the Aristotelian view that knowledge is of causes, which he treated as meaning that knowledge is possible only where we are responsible for the whole construction,

including its most primitive elements. Since God contains eminently the elements of everything within himself, what he knows is both true and real. As part of God's world, we cannot attain such completeness. Nevertheless, through our ability to abstract from God's creation, we can create such fictive elements as mathematical points and lines and from these construct theorems that are true but fictive. Beyond mathematics, however, the sciences become less certain as their subject matter becomes less amenable to the application of mathematically based theory. Hence, mathematics remains the most certain science, followed by mechanics and physics. Human behaviour, governed by caprice and emotion, remains the least certain of all. Here again, the art of topics is required.

This constructivist theory enabled Vico to reject his earlier Cartesian arguments. We cannot start from *Cogito* since, not knowing how mind is made, we can have certainty - that is, the mere inability to doubt - of our existence, but not full causal knowledge of our mode of existence. Nor can we demonstrate the existence of God since any such demonstration would require us to create him. Possibly realizing the difficulty which this claim created for knowledge of his metaphysical theory of the human mind, Vico left knowledge of God to faith and revelation.

The transition to his mature philosophy was occasioned by a close study of Grotius' *The Law of War and Peace* in 1717 (see Grotius). Grotius' purpose was to justify a system of international law by arguing philosophically and historically that it was an extension of a rationality existent universally in the natural law of nations. This gave Vico an insight into a way in which philosophy, which is concerned with the universal, could contribute to an understanding of the nature of the human world. But he advanced two general criticisms of Grotius. First, he had failed to recognize the metaphysical importance of God and the historical importance of the Fall. Second, his historical treatment of law lacked sound principles of historical interpretation, leading to anachronistic accounts of ancient law which assimilated it to that of his own civilized times. Criticism of the historical accounts of other political theorists, particularly Hobbes, Pufendorf and Selden, confirmed Vico's belief that a sound method was required to show how a rational system of law could have developed historically from the Lucretian-style brutes with whom, it was generally agreed, history began (see Lucretius).

His first attempt at such a system came in two large works, *On the One Beginning and One End of Universal Law* (1720) and *On the Constancy of the Jurisprudent* (1721), the second of which was divided into a philosophical and a philological or historical part. The metaphysical theory of human nature still remained, now as the basis for a deduction of the virtues of prudence, temperance and courage and, thence, the authority of law over property, liberty and wardship. The theory of the Fall was also retained to support the idea that the historical state of law (the 'certain') is never purely contingent and unjustifiable because it incorporates a partial and developing degree of rationality left within us after the Fall, the end product of which will be the full development of the concepts of truth and equity.

Vico first tried to give these claims historical support by showing that the history of Roman law could be read in this way, but he soon realized that their universal character could be demonstrated historically only by showing that they applied to the histories of all nations. His attempt to do this, however, in *On the Constancy of the Jurisprudent*, revealed to him that the law of a nation could not be treated in isolation from other fundamental aspects of its life. Hence, in the various versions of the *New Science*, he engaged in the enormous task of showing that there was a common pattern to the development of all the major facets of the histories of the nations. The one exception which he carefully allowed was Jewish history, in order to respect the Biblical account of the Fall.

4 The *New Science*: structure and contents

The *New Science* exists in three editions, written in 1725, 1730 and 1744. The *First New Science* (1725) and *Second New Science* (1730), as they are called, are structurally very different. The *Third New Science* (1744) was an attempt to incorporate into the text of the *Second New Science* many additions and improvements developed after its publication. Since it would be impossible here to treat each separately, what follows is an overview of Vico's main doctrines.

The *New Science* offers an account both of the philosophical foundations, ontological and epistemological, required for an understanding of history and partial demonstrations of certain actual histories. The central ontological claim is that all (gentile) nations share a common nature which is exhibited to a greater or lesser degree

in their actual histories in so far as they are affected by different external contingencies. This nature has two fundamental features. First, it is essentially sociable, expressing itself in a holistic network of cultural and institutional creations. Second, it is essentially developmental. The seeds of justice and truth left within the gentile nations after the Fall are the causes of a development of culture and society, as we pass from an original, nonrational, mythic consciousness to a rational consciousness which is the fulfilment of human nature. Thereafter, however, civilization descends into a state of intellectual and moral depravity, the 'barbarism of reflection', from which it can be saved only by a return to something like the conditions after the Fall and a recurrence of the whole sequence. In its unactualized form this sequence is an 'ideal eternal history', tracing the career of a nation were it governed only by its internal nature. But since the actual histories of nations are affected by many contingent factors, involving physical causes such as geographical conditions, disease, famine or war, there will be no perfect exemplifications of the 'ideal eternal history'. All actual histories will nevertheless be recognizable variants of it. This conception undoubtedly owes something to the influence of Neoplatonism.

Vico gives two reasons for demonstrating that there is such a universal and necessary pattern. First, that its existence proves that there is a Providence which influences human affairs and, hence, that there is a God in whom we should believe. Second, that since it will end in a state of anarchy, an understanding of its underlying causes will enable us to avert ultimate disaster.

5 The *New Science*: structure and contents (continued)

The sequence offered involves three stages of cultural, social and political development, the 'poetic' or 'theological', the 'heroic' and the 'human' ages. The main structure of this process follows the natural order of psychological development worked out in Vico's earlier writings, now, however, taken as psycho-social principles of development. They issue in forms of a 'common sense', or sets of fundamental beliefs about the world, shared by classes within the nation or by the whole nation, which govern the culture and institutions of their age.

The poetic age is the product of the most primitive kind of human being, a brutish, egoistic creature, lacking reason but endowed with huge ideographic imaginative powers, through which is created the first primeval image of the world as a vast animate being, or God. Fear of this God and his children, who successively come into existence as imagistic ways of conceiving new social necessities, dominates every aspect of the culture and institutions of the age, giving rise to the practices of sacrifice and divination and thence to the political supremacy of the priestly classes. As mediators of the divine will, the latter acquire a semi-divine status through which they become the first kings, while law comes into existence as the means of protecting God's mediated ownership. The basis of all this, however, is our primitive capacity to create through imagination and to believe that which is created as literal truth. This is Vico's theory of myth as *vera narratio*: that what has come down to later ages as imaginative fiction was, in its origin, taken as literal truth. Accordingly, the key to understanding the poetic age depends upon taking myths as literal expressions of the way in which the physical and human world was seen and believed. These basic principles also underlie the morality, politics, geography and history of the age. Much of Vico's own account of the character of this age is dependent upon his highly original interpretation of the Homeric poems as later compilations of these original myths.

The 'heroic' age is that in which the kings, through a sequence of traceable steps, progressively lose their unique status. There are two reasons why this occurs. First, because of their corrupt nature, they abuse their powers to the extent that, in order to defend themselves against their subjects, they form political associations with other kings ('aristocratic republics') which weaken their original monarchical status. Second, their increasingly rational subjects realize the falsity of the claim to semi-divine status upon which their privileged political status depends. Thereafter, it is a question of challenging the legal conceptions which their claim to divine origin can no longer justify until, ultimately, a new form of political organization is required, resting upon new conceptions of humanity and justice.

In the 'human' age these developments reach their '*acme*'. The seeds of truth in our original imperfect nature have now developed into a full understanding of the truth: that equity is the supreme and proper principle of law, that human customs should be informed by our sense of civil duty and that governments should be based upon the principle of equality under the law. The human age is not, however, in all ways superior to the earlier ages. One of Vico's fundamental principles is that imagination weakens as reason strengthens. Accordingly, although theologians and philosophers can now prove the truths of (Christian) religion, they cannot implant in the general

public that degree of instinctive belief which arose when God was a product of the primeval human imagination and which once held together whole communities. Thus, the highest stage of human rationality is also the start of a rapid period of moral corruption which will destroy the customs and institutions necessary for the maintenance of social and political order and lead to a new poetic age. Hence, the course of nations will be succeeded by a recourse such as had occurred in feudal Europe, Vico claimed, after the fall of Rome, in which he descried many parallels with the life of early Rome.

Although the ‘ideal eternal history’ outlines the above sequence, in his more detailed explanations of its character Vico makes extensive reference to the operation of certain ‘natural’ principles or ‘necessities of nature’. These are largely certain psychological and psycho-social propensities which belong to us by nature. They are therefore aspects of a ‘metaphysics of the human mind’ which, he claims, is fundamental to his theory. They are used to explain the development of language from the gestures proper to the first poets to the articulated verbal language of the rational age, the parallel developments of ideas from the ideographic images of the poets to the abstract ideas of rational beings and the development of the institutional systems which presuppose them. The fact that the sequence from imagination to reason is itself classified as a ‘natural necessity’ shows that it is not correct, as is sometimes argued, to see the ‘ideal eternal history’, or its exemplifications, as an account of the self-development and subsequent decay of the imagination alone. Despite its undoubted importance in Vico’s conception of human nature, his ‘imagination’ is not the self-transcending imagination of the great Romantics. Rather, it is an imagination which operates according to certain principles of human nature, some of which are most fully explained in *On the Most Ancient Wisdom of the Italians Unearthed from the Origins of the Latin Language*.

This naturalizing tendency in Vico’s account of the basis of the ‘ideal eternal history’ raises vexed questions about the sincerity of his claim to have proved the influence of providence in history and, thereby, the existence of God. Moreover, his distinction between Jewish and gentile history requires a historical interpretation of the Old Testament which is incompatible with his claim to found the principles of true history upon a *universal* metaphysics of the human mind. Unsurprisingly therefore, he often fails to adhere to the distinction, assimilating events in the Old Testament to others in the gentile nations from which they should differ. Consequently, in the face of contemporary suspicions of heresy, he insisted that the sequence traced in the ‘ideal eternal history’ occurs largely through the unintended, rather than the intended, consequences of human action, thus making it possible to attribute the universally patterned nature of their outcome to the influence of Providence. Some interpreters accept this as evidence of the sincerity of his belief in the theological context in which he set his theory. But since he failed to provide any theory to give his claims about Providence explanatory force, it is difficult to believe that the suspicions he sought to allay were unfounded.

6 Theory of historical knowledge

The theory of knowledge which Vico advanced to support his theory of history is an extension of his early *verum-factum* theory: we can know only what we make or do. In his early works, where he lacked a theory of the causes of social and historical change, he had concluded that, because chance and contingency were ineliminable in the world of everyday affairs, knowledge of it was unattainable. In the *New Science*, however, where such theories are advanced, knowledge becomes possible. If human societies develop through the operation of features of human nature which we share, there seems no reason why we should not use our knowledge of them to recreate the past. Hence, Vico could advance his fundamental claim that, since the world of nations has been made by men, its principles are to be ‘rediscovered within the the modifications of our own human mind’. These ‘modifications’ provide components of his ‘metaphysics of the human mind’.

The crux of his later theory of knowledge lies in a mutually supportive relationship between philosophy and philology, the possibility of which he first saw in Grotius. Philosophy contemplates reason and issues in the true; philology is the study of what people have made and done, their particular languages, institutions and deeds, that is, the ‘certain’. When correctly conceived, philosophy should seek formal and substantive principles for the interpretation and explanation of human history, while philology will reach historical truth through its consistent application of these principles. The central idea, therefore, is that philosophy should produce fundamental theories about human nature and the substantive principles which underlie human historical development, culminating in the ‘ideal eternal history’, in the light of which fragments of historical data can be interpreted and integrated into comprehensive and coherent accounts of the actual historical past. Philosophy does not establish its theories a

priori, however, but through its success in finding a set of universal and necessary principles of which all actual histories are an expression. This conception lies behind the widespread comparative enquiries into the history of thought, languages and institutions in general, which abound in the *New Science*.

Once again, however, Vico's claims about Providence are problematic since if, as he consistently asserts, it affects the process of historical development, its workings will be unintelligible to us. The difficulty is not simply that of understanding a history in which the unintended consequences of individual human actions produce similar patterns of development in different nations. This can be explained by Vico's theory of a common sense, arising from the common nature of nations, which ultimately determines shared social decisions. If Providence is seen as nothing more than common sense, indeed, the problem disappears, but so also does the claim to have demonstrated the existence of God. If, on the other hand, Vico's insistence that Providence is something over and above common sense is genuine, as some commentators claim, there will be something at work in the historical process which is not of human construction and which we therefore cannot know. Vico's claims about Providence are therefore incompatible with his theory of knowledge. This lends support to interpretations which are sceptical of his theistic claims.

A different problem derives from Vico's vacillations about the status of the products of philosophy. In the *First New Science* he refers to them as metaphysical truths but does little to establish them. In the later versions, he describes them as hypotheses which, through confirmation, will attain the status of metaphysical truths. The suggestion here is that they originate as hypotheses and gain their entitlement to truth as a result of their interpretative and explanatory fruitfulness for the historian. In this case it might be questioned whether they are metaphysical at all. But it could equally well be argued that there is no way of establishing the truth of a wide-ranging hypothesis about reality other than by testing its capacity to inject coherence into a fundamental aspect of human experience. This seems to be what Vico finally had in mind.

7 Ultimate doubts

Vico was confident that he had produced a science which would enable us to understand the truth of human history but he became much less certain that this would enable us to diagnose the ills of our society or to remedy them. His suggestions for averting final political and social disaster - the maintenance of law by power of arms under the shield of religion, conquest by another nation or a return to conditions similar to those of the poetic age and a recurrence of the whole cycle - are so unconvincing as to seem little more than expressions of his own perplexity. Nor is this difficult to understand. For if, as he claims, imagination weakens as reason strengthens and if effective religious belief as the main social bond depends upon imagination, then, as soon as the age of reason is reached, religion and social cohesion are bound to decline and there will be no basis for the shield of religion or the other social bonds.

These doubts depend, however, upon a gratuitous inconsistency in his thought. The anarchy in which the life of a nation ends presupposes an incompatibility between imagination and reason. But Vico's general theory requires that they be able to coexist and cooperate, one for the creation of systems of belief, the other for their critical assessment. Without both, indeed, the heroic age would never be superseded. For it is only because the lower classes see the falsity of the imaginary claim to divine origin, which is the basis of the nobility's privileged legal and political status, that the latter becomes challengeable. Thus imagination and reason cannot be incompatible in the way implied by Vico's final doubts. Had he realized this he would have seen no need to postulate either the 'barbarism of reflection' or the recurrence of the life cycle of the nation.

8 Influence

The obscurity of Vico's life and thought has made the extent of his influence upon later thinkers difficult to trace. His emphasis upon the internal coherence of the culture and institutions of different historical societies based upon shared modes of thought and feeling has striking similarities with the thought of Hamann, Herder, Hegel and Marx, of whom only Hegel seems almost wholly ignorant of him. His most direct influence in the nineteenth century was upon Michelet, Comte, Coleridge, Croce and Sorel. In this century he has influenced a number of writers, including Berlin, Collingwood, Gadamer, Joyce and MacIntyre. But there is considerable circumstantial evidence to suggest that he may have influenced many others interested in general theories of the development of civilization from Adam Ferguson and Rousseau onwards.

Vienna Circle

The Vienna Circle was a group of about three dozen thinkers drawn from the natural and social sciences, logic and mathematics who met regularly in Vienna between the wars to discuss philosophy. The work of this group constitutes one of the most important and most influential philosophical achievements of the twentieth century, especially in the development of analytic philosophy and philosophy of science.

The Vienna Circle made its first public appearance in 1929 with the publication of its manifesto, The Scientific Conception of the World: The Vienna Circle (Carnap, Hahn and Neurath 1929). At the centre of this modernist movement was the so-called 'Schlick Circle', a discussion group organized in 1924 by the physics professor Moritz Schlick. Friedrich Waismann, Herbert Feigl, Rudolf Carnap, Hans Hahn, Philipp Frank, Otto Neurath, Viktor Kraft, Karl Menger, Kurt Gödel and Edgar Zilsel belonged to this inner circle. Their meetings in the Boltzmanngasse were also attended by Olga Taussky-Todd, Olga Hahn-Neurath, Felix Kaufmann, Rose Rand, Gustav Bergmann and Richard von Mises, and on some occasions by visitors from abroad such as Hans Reichenbach, Alfred Ayer, Ernest Nagel, Willard Van Orman Quine and Alfred Tarski. This discussion circle was pluralistic and committed to the ideals of the Enlightenment. It was unified by the aim of making philosophy scientific with the help of modern logic on the basis of scientific and everyday experience. At the periphery of the Schlick Circle, and in a more or less strong osmotic contact with it, there were loose discussion groups around Ludwig Wittgenstein, Heinrich Gomperz, Richard von Mises and Karl Popper. In addition the mathematician Karl Menger established in the years 1926-36 an international mathematical colloquium, which was attended by Kurt Gödel, John von Neumann and Alfred Tarski among others.

Thus the years 1924-36 saw the development of an interdisciplinary movement whose purpose was to transform philosophy. Its public profile was provided by the Ernst Mach Society through which members of the Vienna Circle sought to popularize their ideas in the context of programmes for national education in Vienna. The general programme of the movement was reflected in its publications, such as the journal Erkenntnis ('Knowledge', later called The Journal for Unified Science), and the International Encyclopedia of Unified Science. Given this story of intellectual success, the fate of the Vienna Circle was tragic. The Ernst Mach Society was suspended in 1934 for political reasons, Moritz Schlick was murdered in 1936, and around this time many members of the Vienna Circle left Austria for racial and political reasons; thus soon after Schlick's death the Circle disintegrated. As a result of the emigration of so many of its members, however, the characteristic ideas of the Vienna Circle became more and more widely known, especially in Scandinavia, Britain and North America where they contributed to the emergence of modern philosophy of science. In Germany and Austria, however, the philosophical and mathematical scene was characterized by a prolongation of the break that was caused by the emigration of the members of the Vienna Circle.

1 Scientific philosophy and philosophy of science

Proponents of 'scientific philosophy' think of philosophy not as an autonomous discipline prior to the sciences but as a critical discipline dependent upon the natural and social sciences, logic and mathematics. Changing a motto of Kant, they hold that philosophy without science is empty, science without philosophy is blind. Adoption of this scientific conception of philosophy does not, however, determine the details of one's epistemology, methodology and ontology. As far as epistemology is concerned, the Austrian tradition offers the contrasting examples of the phenomenology of Franz Brentano and the positivism of Ernst Mach. Similarly, there are those who stress the unity of the natural and the social sciences and those who contrast explanation in the natural sciences with the distinctive type of understanding (*verstehen*) characteristic of human affairs. Finally, both idealist and materialist ontological positions are compatible with this understanding of philosophy. Nonetheless all proponents of scientific philosophy demand exact methods and an empirical orientation. They oppose irrational and theological systems of philosophy with an attitude that shows their commitment to the ideals of the Enlightenment and to science.

Historically, the positivism of Mach's scientific philosophy was the most important precondition for the development of the position adopted within the Vienna Circle. The term 'philosophy of science' was used to describe this position, but by this was meant a general scientific conception of philosophy as well as a commitment

to providing a philosophy of the sciences. Thus within the Vienna Circle, philosophy was regarded both as a general analytic and language-oriented activity and as a discipline working on the foundations of the natural and social sciences. At the same time we find within the Vienna Circle those such as Moritz Schlick who defend a methodological dualism of philosophy and science, and those such as Otto Neurath who seek to absorb philosophy altogether within a scientific conception of the world. Independent of this variety of positions, however, empiricism, an orientation towards the sciences, and an exact logical-mathematical methodology remain essential features of the Vienna Circle.

2 Logical positivism

The name ‘Vienna Circle’ was used in public for the first time in 1929 in the programmatic essay *The Scientific Conception of the World: The Vienna Circle* (Carnap, Hahn and Neurath 1929). It was suggested by Neurath and was supposed to have pleasant connotations similar to ‘Vienna Woods’ or ‘Viennese Waltz’. At the same time the term should indicate the origin of this philosophical movement and its collective orientation (Frank 1949), although strictly speaking, it is anachronistic to use it for the period before 1929. In this programmatic essay the position of the ‘radical’ wing around Neurath, Carnap, Hahn, Frank and others was especially prominent. This wing, institutionalized in the Ernst Mach Society, supported the idea of a unified physicalist science as represented in the programme of the *International Encyclopedia of Unified Science*. By contrast the more moderate wing of the Vienna Circle around Schlick, Waismann, Feigl and others - in fact the majority - emphasized their adherence to a dualism of science and philosophy with changing names like ‘consistent empiricism’, ‘logical empiricism’, or ‘logical positivism’.

The widely used term ‘logical positivism’ comes in fact from Albert Blumberg’s and Herbert Feigl’s paper ‘Logical Positivism: a New Movement in European Philosophy’, published in the *Journal of Philosophy* in 1931. Blumberg and Feigl give a concise description of the new synthesis of logical and empirical factors:

> The new logical positivism retains the fundamental principle of empiricism but… feels it has attained in most essentials a unified theory of knowledge in which neither logical nor empirical factors are neglected. From the point of view of logical positivism, the Kantian synthesis concedes too much to rationalism by assuming the existence of synthetic a priori truths. Against Kant the new movement maintains as a fundamental thesis that there are no synthetic a priori propositions. … it holds that factual (empirical) propositions though synthetic are a posteriori, and that logical and mathematical propositions though a priori are analytic.
>
> … By means of the theory of knowledge thus constructed, logical positivism … shows that the propositions of metaphysics, in most senses of the term, are, strictly speaking, meaningless.
>
> (Blumberg and Feigl 1931: 282)

Blumberg and Feigl go on to describe the philosophical transformation from old to new positivism with the adoption of symbolic logic, epistemology, and research into the foundations of science. Finally, they explain, following Wittgenstein, their notion of philosophy: ‘The purpose of philosophy is the clarification of the meaning of propositions and the elimination of… meaningless pseudo-propositions’ (Blumberg and Feigl 1931: 269). Despite its widespread currency, however, the term ‘logical positivism’ has the disadvantage that it associates the Vienna Circle too closely with positivism, and thus, for example, with the ‘positivism dispute’ that runs from Lenin to the Frankfurt School. Hence the term ‘logical empiricism’ is now often preferred: it takes into account the synthesis of rationalism and empiricism, and signals clearly the two most important elements in the philosophy of the Vienna Circle.

In Schlick’s logical empiricism the classical philosophical positions of empiricism and rationalism were integrated with the help of modern logic and mathematics, but a distinction between philosophy and science was still admitted. Neurath’s more radical ‘scientific conception of the world’ aimed at overcoming philosophy itself within his scheme for a unified physicalist science. This divergence in philosophical approach left room for debates within the Circle on such topics as the merits of phenomenalist and physicalist languages, coherence and correspondence theories of truth, logical syntax and semantics, verification and confirmation, and ideal and natural languages. At the same time there was a consensus concerning the merits of a logical analysis of language, a fallibilist epistemology, a scientific attitude to the world and the unity of scientific explanation and knowledge in general. After Schlick’s death, however, his logical empiricist project collapsed following personal and theoretical

disagreements. The project of a unified science, however, continued in the unity-of-science movement (see §4).

An important element of the logical empiricism of the Vienna Circle was the refusal to accept synthetic judgments a priori. Following Russell and Whitehead, symbolic logic and mathematics were regarded as purely analytic (because merely 'conventional') and a priori (and thus independent of any experience). Analytic truths of these kinds were contrasted with empirically true statements of the natural sciences and ordinary experience; these were synthetic judgments a posteriori. But there was no further class of synthetic a priori judgments; instead there was thought to be an important class of 'meaningless' sentences. The elements of this class, being neither analytic nor synthetic a posteriori, are 'metaphysical' in a sense which implies that they are not part of knowledge at all even though they may express some realm of experience. This anti-metaphysical position of the Vienna Circle is most prominently represented by Rudolf Carnap's 'Elimination of Metaphysics Through Logical Analysis of Language' (Carnap 1931). It prepares the logical empiricist programme for a unified reconstruction of science. But the question whether an empirical basis could be a foundation for all knowledge received strongly divergent answers from the coherence theorists around Neurath and the correspondence theorists around Schlick (Hempel 1981; 1993). The apparently strict distinction between analytic and synthetic sentences had also already been questioned (Menger 1979; 1994). Indeed, the ideal of one language of science, logic and mathematics had already been strongly relativized by the Vienna Circle itself, long before Quine put forward his classic critique (Quine 1953). Thus, contrary to its popular reputation, a heterogeneous pluralism of views was in fact characteristic of the Vienna Circle: for example in questions of ethics (Schlick 1930; Menger 1934; Kraft 1937), in regard to 'realism' versus 'positivism' (Schlick 1933; Carnap 1928; Feigl 1929; Kraft 1925), verificationism versus falsificationism (Neurath 1935), and not the least in questions of an ideological and political nature.

3 Logical empiricism and the scientific conception of the world

The relationship between Schlick's logical empiricism and Neurath's distinctive scientific conception of the world is a complex matter. Certain points are of course held in common, such as the view of philosophy as a language-oriented, analytic activity. Again, the principle of verification ('The meaning of a sentence can be given only by giving the rule of its verification.') (Schlick 1938: 341; Hempel 1950), logical atomism (following Russell) and the picture theory of language (following Wittgenstein's *Tractatus*), are constitutive features of the entire movement but are in themselves insufficient for its characterization. Kamitz (1973), mainly referring to Carnap's positions, characterizes the Vienna Circle up to about 1930 by the following principles: the formal character of mathematics (Logicism: that is, subordination of mathematics under logic which itself is purely analytic), verifiability, methodological phenomenalism (Carnap's epistemological position in *The Logical Construction of the World*), and 'scientism', which is a claim to the omnipotence of science when compared with alternative forms of knowledge in philosophy and art. For the period 1930-5 the following principles are listed: the hypothetical character of empirical claims (the criterion of verifiability is replaced by a criterion of confirmability), the conventionalist interpretation of logic, physicalism as the foundation of the unified science (a physicalist, quantitative, empirical language as unifying intersubjective language of science), and the conception of philosophy as logical syntax of the language of science. These principles reflect the growing dominance of Neurath's point of view within the Circle. In particular, the last principle restricts questions of truth to comparisons among sentences along the lines of Neurath's coherence theory in order to avoid the dualism of 'language' and 'world' suggested by the correspondence theory of truth. In line with this, Carnap and Neurath deny any absolute 'foundation of knowledge' of the kind sought by Schlick (Schlick 1934). They hold that in any empirical justification it is not single sentences that are tested, but whole systems of sentences, and science in general. This is a form of relativism that makes Neurath in particular a forerunner of recent holistic approaches in philosophy of science (see Hempel, Popper and others in Skirbekk 1977).

Although this last point of view is distinctive of Neurath, it is important to grasp that the 'scientific conception of the world' which he and others promulgated within the Circle had a much broader cultural goal. It was not simply a neo-positivist anti-metaphysical scientistic programme. Instead he looked to a unified science and a truly scientific conception of the world to make everyday life more humane and democratic. In portrayals of the Vienna Circle written after the Second World War these practical aspirations are often treated as inessential political ambitions when compared with the scientific programmes of logicism and empiricism, whereas in fact internal debates about them were emphasized and regarded as characteristic of the Vienna Circle. We find the clearest presentation of the claim to social reform that is inherent in the scientific conception of the world in the

programmatic essay of the Vienna Circle of 1929:

> The endeavour is to link and harmonise the achievements of individual investigators in their various fields of science. From this aim follows the emphasis on collective efforts, and also the emphasis on what can be grasped intersubjectively; from this springs the search for a neutral system of formulae, for a symbolism freed from the slag of historical languages; and also the search for a total system of concepts. Neatness and clarity are striven for, and dark distances and unfathomable depths rejected. In science there are no 'depths'; all is on the surface. Experience forms a complex network, which cannot always be surveyed and can often be grasped only in parts. Everything is accessible to man; and man is the measure of all things.... The scientific conception of the world knows no unsolvable riddle.
>
> (Carnap, Hahn and Neurath [1929: 15] 1973: 305)

This concluding paraphrase of one of Wittgenstein's claims in the *Tractatus* is the starting point for this late Enlightenment programme of science with its anti-metaphysical orientation. Traditional philosophy with its mannerisms has, in a first step, to be reduced to a critical analysis of language:

> No special 'philosophic assertions' are established, assertions are merely clarified; and at that assertions of empirical science. ... Whichever term may be used to describe such investigations, this much is certain: there is no such thing as philosophy as a basic or universal science alongside or above the various fields of the one empirical science.
>
> (Carnap, Hahn and Neurath [1929: 28] 1973: 316)

The practical impulse behind this therapeutic destruction of a philosophy of metaphysical systems and the rational subject was the desire for a unified and empirical conception of the world on the basis of simple human experience, directed against the 'Zeitgeist' of an increasing number of metaphysical movements whose rise was connected with social and economic factors. Social criticism thus becomes an accompaniment of empirical science and replaces the classical philosophical materialism of the labour movement:

> In previous times, materialism was the expression of this view; in the meantime, however, modern empiricism has shed a number of inadequacies and has taken a strong shape in the scientific conception of the world.
>
> (Carnap, Hahn and Neurath [1929: 29] 1973: 317)

Its closeness to real-life issues and its solidarity with the forces of progress led in the time of emerging fascism to an aggressive determination of its position on social issues:

> We witness the spirit of the scientific conception of the world penetrating in growing measure the forms of personal and public life, in education, upbringing, architecture, and the shaping of economic and social life according to rational principles. The scientific conception of the world serves life, and life receives it.
>
> (Carnap, Hahn and Neurath [1929: 30] 1973: 317)

Social criticism, sociology of knowledge, and philosophic-scientific collective work formed in this conception a programmatic unity in hope of comprehensive progress, which was partly put into practice. But whereas in the natural sciences, Neurath thinks, considerable progress has already been achieved, the situation in the social sciences is less clear ([1930-1: 121] 1983: 44). Neurath therefore attempts in his *Empirical Sociology* (1931) to give a 'physicalist' description of the processes of human social interaction, of the forces that make groups of people cooperate or work against each other and of their influence on the lives of the masses. And his general attitude towards long-term predictions of social sciences is manifested in his cautiously optimistic outlook on possible future developments of society and science (which can nowadays look rather utopian). In this respect it is worth mentioning that after the disintegration of the Vienna Circle (which was also a process of political neutralization) reference to the 'scientific conception of the world' was occasionally used by former members of the Vienna Circle in connection with general ideological questions. For example, Carnap (1963: 81) talks about 'scientific humanism' as a view shared by the majority of the members of the Vienna Circle. By this he means, first, that everyone determines their own life, second, that mankind has the ability to improve their conditions of living and, third, that every liberating action presupposes knowledge about the world, knowledge that is best achieved by scientific means, so that science becomes the most important instrument for an improvement of our lives. According to Carnap, such aims require rational planning which in turn would be best achieved by some

form of socialism and a world-government.

4 *Encyclopedia of Unified Science*

After the dissolution of the Vienna Circle, the forced emigration of most of its members, and the diffusion of the logical empiricist movement from its centres in Vienna, Prague and Budapest, the twin aims of a transformation of philosophy and the establishment of a scientific conception of the world could be envisaged only without reference to their previous cultural context and audience. But even in these difficult times Neurath and his circle still succeeded in organizing well-attended conferences of high standard ('International Congresses for the Unity of Science'), and he also managed to ensure that the unity of science movement continued in the USA (Neurath, Carnap and Morris 1970-1) (see Unity of science). After 1935 Neurath devoted himself to the model of the 'encyclopedia' as a means for furthering this movement. In cooperation with Carnap, Frank and Morris, he planned an international encyclopedia of the unified science and, corresponding to it, worked on a picture language (Isotype) of visual representation. He presented this programme as a development of the ideas of the philosophers of the French Enlightenment. This vision of an unfinished Enlightenment project remains today a striking challenge for the scientific community.

Villey, Michel (1914-88)

Michel Villey was France's leading post-war philosopher of law in the 'natural law' mode. He aimed to rediscover a distinctively philosophical approach to law rooted in the history both of legal ideas and of legal institutions. Legal institutions he considered to have been uniquely a gift of Greco-Roman civilization to the world. They represent a distinctive domain of human activity, concerned with an objectively just ordering of human relationships as these affect external conduct and the possession and use of things. Villey has in common with legal positivism a belief in the differentiation of the legal, concerned with objective interpersonal relations in their 'external' concern with a distribution of things, from morality and from religion with their distinctively 'internal' and 'spiritual' concerns. In opposition to legal positivism, however, he holds that justice is a concept implicit in the legal, and discountenances positivists' tendency to reduce law to a simple aggregation of enacted statutes.

Villey poses the Aristotelian question: what is the defining end of the legal that gives it its distinctive character? His answer is: that of upholding order by settling conflicts of interest among the members of a human society. Law's particular aim is towards objective conflict-resolution in respect of the 'things', corporeal or incorporeal, in which humans take an interest. What law seeks is a just allocation or reallocation of things to persons, in the context of some concrete controversy over their rightful allocation.

This is a creative art, not a science. Guided by the equity of concrete human relations, the judge has to work out creatively the right allocation of things in issue (see Justice, equity and law). This right resolution ('*le droit*', 'the right' in an objective sense) has to be guided by any relevant enacted laws. But in any seriously disputed case, rival rules of statute-law can be advanced by rival parties, and the judge must still choose. Further guidance is to be drawn from contemporary custom and from judicial precedents. These, too, are genuine parts of the law, in opposition to the ideas of merely voluntaristic positivists, who reduce law to being no more than the total body of the statutes in force. But even when custom and precedent are brought in, they only define further the whole context in which the relations of the parties must be considered with a view to reaching the equitable resolution of their conflict, the right of the matter in an objective sense. This objective character of the right Villey regarded as the deepest element implicit in a Thomistic understanding of law. He considered it hostile to the subjectivism implicit in contemporary ideas of human rights, which in his view constituted an ideology inimical to legal order properly conceived.

Villey's version of Thomistic philosophy is an adventurous and highly contestable reading of the texts; but it constitutes an original contribution to natural law thought, and shows in an interesting way the possibility of using natural law premises to cast doubt on contemporary views of human rights.

Violence

Violence is a central concept for much discussion of moral and political life, but lots of debate employing the concept is confused by the lack of clarity about its meaning and about the moral status it should have in our development of public policy. Wide understandings of the term - for instance, structural violence - not only include too much under the name of violence, but also put an excessively negative moral loading into the concept. This is also a problem for some other definitions of violence, such as legitimist definitions, which treat violence as essentially the illegitimate use of force. It is better to confront directly the important and disturbing claim that violence is sometimes morally permissible than to settle it by definitional fiat.

1 Definitions and paradigms

In discussing violence, it helps to begin with some obvious pre-theoretical examples, such as knife attacks, savage beatings, shootings, bombings and torture. Offering such cases may be insufficient for the definitional clarification of the concept that we seek as philosophers, but these paradigms can fix our attention on at least part of what is to be made clear. If theorists claim that these are not acts of violence, then they have some explaining (or theorizing) to do.

In fact, some theorists seem to claim precisely this, while others claim that, although the above list is correct as far as it goes, there are some more surprising candidates for inclusion as paradigms. Both groups seem to suffer from a certain disdain for communicative clarity, but, more importantly still, from a tendency to overmoralize the concept. Since the idea plays a crucial role in a wide range of significant moral and political debates, it is imperative to be clear about what we mean by the term and what sort of evaluative loading it carries.

2 Two theories and their difficulties

To elaborate on this point, it is significant that, although the tendency to eliminate some of the paradigm cases and the tendency to add surprising ones usually spring from very different political motivations, both draw upon the idea that violence is inherently wrong. We can see this if we examine two theories that embody these different tendencies. Legitimists about violence instantiate the first tendency and proponents of the notion of structural violence embody the second. Legitimist definitions treat violence as the *illegitimate* use of force. Characteristically such an approach is associated with politically conservative outlooks, but this is a psychological rather than a logical connection. A major problem for these thinkers is that they have considerable difficulty explicating a theoretically helpful sense of legitimacy. Most of them employ a norm of political legitimacy (as is clear in Sidney Hook’s definition of violence as ‘the illegal employment of methods of physical coercion for personal or group ends’ (Grundy and Weinstein 1974: 12)), but they also think of this as having some moral underpinning, and hence tend to treat violence as essentially in the category of wrongs. In a legitimate state, properly authorized employment of shooting or savage beating by police will not then count as violence since it is a politically legitimate use of force. But there are obvious problems about distinguishing its various types (*de facto*, *de jure*, internationally recognized though internally contested, and so on) and it is also hard to avoid the awkward consequences that the state of nature, even understood in Hobbes’ extreme terms, cannot be a state of violence (since the ideas of political legitimacy or illegitimacy do not apply), and that warfare between two legitimate states cannot involve violence. In the latter case, both states will usually be engaged in the politically legitimated use of force which, by definition, cannot be violence. It is unlikely that this conceptual apparatus could help in the practical discussion of moral limits to police violence or the conduct of war (see War and peace, philosophy of §§1-2, 6). If, on the other hand, in the face of the problems posed by resort to political legitimacy, moral legitimacy is invoked, then justified killing in self-defence or defence of innocent others will not involve violence and all violence will be morally illegitimate by explicit definition, which represents the serious fudging of a central question.

By contrast, the concept of structural violence, much in vogue with the political left, flaunts intuition, not by excluding what seem to be obvious candidates, but by bringing into the category of violence a wide range of things that would not, at first, be included. This definitional proposal springs from the work of the Norwegian sociologist Johan Galtung (1969) and the basic idea is that we should use the term violence in a very wide and extended way to refer to any form of social injustice whether inflicted by individuals or by institutions or by the workings of

society at large, and whether or not it involves the deliberate infliction of personal injury by episodes of physical or psychological force. Such episodes would be merely one type of violence. Advocates of this wide definitional strategy tend to argue that standard definitions of violence focus too much upon the harms intentionally inflicted by the personal employment of physical force. Since these instantiate only one type of damage that human contrivance can inflict, why not use the term violence to cover all such damage? This style of proposal faces several difficulties: it is confusing, politically unhelpful and evades a central problem about violence.

It is confusing because people do not ordinarily mean by 'violence' any and every form of social injustice, they mean such things as beating people up or torturing them with electrodes. They do not mean to refer to iniquitous taxation proposals or discriminatory housing policies. These things may lead to violence or they may need violence, or the threat of it, to sustain and implement them, but that is another matter. It may be argued that violence is a bad thing, but it is just confusing to treat every bad thing as violence. Moreover, the expansive sense of violence does not help with an agenda of social reform, because it encourages the cosy but ultimately stultifying belief that all social evils are really one and hence will yield to the one solution. The reality seems far more likely to be that the various problems we face are genuinely diverse, although related in various ways, and have their own specific features that call for detailed study with a view to solution. Better gun control legislation might well alleviate problems of violence in the USA while doing nothing to change poverty levels. Furthermore, the proponents of the concept of structural violence assume that violence is essentially morally wrong, and seek broad support for various social reforms by claiming that they will eliminate (structural) violence. But this assumption is contentious. It may be that there is something about violence which makes resort to it always, in certain ways, regrettable, while none the less, at times, it can be argued to be morally legitimate, even morally required. These issues need to be faced, not evaded.

3 The restricted definition

It is therefore preferable to operate with a concept of violence which is both narrower than that of structural violence and less morally loaded than either it or the legitimist definitions. Initial guidance is provided by such dictionary definitions as that of the *Oxford English Dictionary*: 'The exercise of physical force so as to inflict injury on or damage to persons or property'. Yet this is arguably too restrictive in excluding psychological violence since we can give some sense to the idea of damage being inflicted by psychological force. Cases of psychological pressure producing overpowering effects seem close to the paradigms given earlier, as, for example, when a parent cruelly humiliates a vulnerable child to the point of collapse or great distress. There is a tendency in the literature to slide from psychological violence to structural violence, but this embodies a confusion since it rests on the tendency to think of psychological violence as *impalpable* and then to feel that its admission endorses the even more impalpable structural violence. However, the examples which make the category of psychological violence plausible are all very palpable indeed, involving an immediacy and specificity of pressure producing overwhelming effects on the victim. The term 'verbal violence' is sometimes used merely metaphorically, but it can make literal sense in contexts where it is a species of psychological violence, and where the term 'tongue lashing' becomes strictly appropriate.

It is worth noting that a 'restricted' definition of this sort is not entirely 'descriptive' or morally neutral although it is much less morally loaded than the other definitions discussed above. It contains reference to the notions of injury or damage which are at least evaluative with respect to some notion of normal or proper functioning. In addition, these notions have complex relations to such centrally moral concepts as harm and autonomy. The conceptual structure of the definition therefore allows us insight into much that is otherwise puzzling about our attitudes to violence, and helps explain some of the appeal of the structural and legitimist outlooks as well as the nature of the distortions they produce. In particular, it helps show why many people have a strong tendency to think that violence is always wrong and that it is none the less sometimes morally right. This tendency is partly attributable to the fact that violence inherently involves the intentional infliction of injury or damage, and we have a strong tendency to equate this with the infliction of harm or wrong. At the same time, most of us recognize that the police, for instance, are sometimes justified in killing or wounding criminals to prevent violent attacks upon innocent civilians or upon the police themselves. There can be problems about the too-ready resort to violence by police, but there is nothing imaginary or fantastic about the circumstances in which such resort seems morally justifiable. In Melbourne, in December 1994, a man ran amok with a semi-automatic weapon in a suburban street, killed two perfect strangers and kept firing at police and passing motorists until a police marksman shot him dead.

Such criminals are certainly injured, but they are not wronged or, in the morally significant sense, harmed.

4 More benefits of the restricted definition

Another problem that can be clarified by the restricted definition is that of violent sports that involve the consent of their participants. Some have thought that boxing, for instance, cannot be violent because the fighters mutually agree to bombard each other with punches; they are influenced by the idea that some action affecting another cannot constitute a wrong or a harm if the other consents to it. Whatever one thinks of that principle, it cannot affect the question of whether hitting someone very hard on the head with the intention of rendering him unconscious is a violent act, at least if we understand violence in the restrictive manner. Anyone so acting is clearly aiming to inflict an injury.

Moreover, the restricted definition helps elucidate two other features of violence which are otherwise puzzling; namely, the point of having such a concept and the fact that even justified violence is regrettable. On the first issue, it is clear that many of us have a distinctive fear of the intrusion into our lives of those intent upon the forceful infliction of injury upon us. We also fear the effects of natural disasters, diseases, social prejudice and injustice, indifference and accident, but our fear of violence usually has a quite particular significance because we are understandably anxious about damage that is specifically directed against us and that is aimed at immediate and dramatic impairment of our wellbeing. This combines with the fact that even justified resort to violence carries with it problems of misjudgment and escalation, as well as the possibility of disturbing psychological consequences for those who employ it, to make the use of violence regrettable even where it is not immoral.

Virtue epistemology

'Virtue epistemology' is the name of a class of theories that analyse fundamental epistemic concepts such as justification or knowledge in terms of properties of persons rather than properties of beliefs. Some of these theories make the basic concept constitutive of justification or knowledge that of a reliable belief-forming process, or a reliable belief-forming faculty or, alternatively, a properly functioning faculty. Others make the fundamental concept that of an epistemic or intellectual virtue in the sense of virtue used in ethics. In all these theories, epistemic evaluation rests on some virtuous quality of the person that enables them to act in a cognitively effective and commendable way, although not all use the term 'virtue'. The early, simple forms of process reliabilism are best treated as precursors to virtue epistemology since the latter arose out of the former and has added requirements for knowledge intended to capture the idea of epistemic behaviour that is subjectively responsible as well as objectively reliable.

Proponents of virtue epistemology claim a number of advantages. It is said to bypass disputes between foundationalists and coherentists on proper cognitive structure, to avoid sceptical worries, to avoid the impasse between internalism and externalism, and to broaden the range of epistemological inquiry in a way that permits the recovering of such neglected epistemic values as understanding and wisdom.

1 History of virtue epistemology and its varieties

Virtue epistemology focuses on traits of persons or their faculties or psychological processes in the analysis of basic epistemic concepts such as justification or knowledge. It is a reaction to a style of epistemology that makes properties of individual beliefs and evidential relations between beliefs the focus of analysis. The theories in the latter category often handle epistemic evaluation on the model of deontological ethics (see Deontological ethics). To be justified, a belief must not violate any epistemic rules or duties - it must be held for the right reason. In contrast, many forms of virtue epistemology have arisen out of reliabilism. According to reliabilist theories, what makes a true belief an instance of knowledge or, alternatively, what makes a belief justified is that it was formed by a reliable process for obtaining the truth (see Reliabilism). Reliable processes include perception and memory whose reliability need not be cognitively accessible to the believer, and so reliabilism is a form of externalism whereas, typically, deontological theories are internalist (see Internalism and externalism in epistemology). Reliabilism is structurally parallel to consequentialist ethics, in particular rule utilitarianism. In a reliabilist theory, the consequences (a high proportion of true beliefs) make a belief process reliable just as in a rule-utilitarian theory the consequences (a high proportion of utility maximizing actions) make a rule a good one. A belief is epistemically justified (alternatively, warranted) by being the product of a reliable truth-producing process, just as an act is morally justified by being the product of a reliable utility-maximizing rule (see Consequentialism).

An advantage of reliabilism is that its requirements for knowledge are relatively easy to satisfy in ordinary circumstances, even by young children and unsophisticated adults. Hence it is often considered closer to common sense than the more rigorous deontological theories. Some theorists also think it has an advantage with respect to avoiding scepticism. For one has knowledge as long as there is no Cartesian demon and one's cognitive processes do, as a matter of fact, reliably hook up with the truth, whether or not one has an answer to the sceptical challenge (Greco 1992).

Since reliabilism shifts the focus of analysis from properties of beliefs to properties of the believer it sets the stage for a form of epistemology that makes fundamental the virtues and vices of a person. It is not uncommon, then, to classify the more recent forms of reliabilism as virtue epistemology (Kvanvig 1992; Greco 1992), and in one place Alvin Goldman classifies his later version of process reliabilism as a form of virtue epistemology (1992). Simple reliabilism, however, is only distantly related to any kind of virtue ethics. A reliable belief-forming process has little in common with the traditional notion of a virtue and, as already pointed out, reliabilism is structurally parallel to consequentialist ethics, not virtue ethics.

Act-based moral theories such as consequentialist and deontological theories make the central concept that of the right act. Similarly, reliabilist and deontologial theories in epistemology make the central concept that of a belief that is justified or, alternatively, warranted (possessing the property that converts true belief into knowledge). A virtue ethic, in contrast, makes the primary concept that of a virtue. The concept of a right act is derivative and is

often less important. A moral virtue is defined neither in terms of the consequences of the acts to which it gives rise, nor in terms of the rules or principles followed by persons exhibiting the virtues. A virtue includes dispositions to have certain emotions as well as dispositions to act in certain ways, and in its Aristotelian and neo-Aristotelian forms virtuous traits are closely tied to a teleological understanding of human nature (see Virtue ethics).

Given this account of the characteristics of virtue ethics, the epistemic parallel would be one in which intellectual virtue is the fundamental concept, and the concept of a justified belief is derivative and may also be less important. A property is not an intellectual virtue simply because of its propensity to produce true beliefs, nor is it a virtue because it involves following epistemic rules or principles. The parallel with virtue ethics would be even closer if an intellectual virtue includes emotion-dispositions as well as dispositions to act cognitively in certain ways, and a neo-Aristotelian form of virtue epistemology would include a connection between epistemic goods and the good life.

While simple reliabilism is quite a distance from virtue epistemology as just described, recent theories have increasingly moved in that direction. Ernest Sosa (1980) first introduced the concept of intellectual virtue into contemporary literature as a refinement of reliabilism. Sosa proposed that the concept of an intellectual virtue can be used to bypass the dispute between foundationalists and coherentists about the logical or evidential relations needed for proper cognitive structure (see Knowledge, concept of §4). What Sosa meant by an intellectual virtue was a reliable belief-forming faculty like eyesight or memory, and he defined such a virtue in terms of its consequences: 'An intellectual virtue is a quality bound to help maximize one's surplus of truth over error' (Sosa 1985: 227). In subsequent work, Sosa (1991) has distinguished animal knowledge from reflective knowledge. For the former it is sufficient that the belief was caused by a reliable truth-producing faculty. For the latter he adds an internalist component. The believer must have a reliable grasp of the fact that their belief is grounded in a reliable cognitive faculty. Sosa also ties the concept of an intellectual virtue to the 'inner nature' of the knowing subject. These recent moves bring Sosa's concept of an intellectual virtue closer to the traditional notion of virtue as used in ethics.

2 History of virtue epistemology and its varieties (cont.)

A version of virtue epistemology that moves even closer to virtue ethics is Alvin Plantinga's theory of warrant as proper function (1993b). Plantinga uses the term 'warrant' for that property which in sufficient quantity converts true belief into knowledge. A warranted belief, according to Plantinga, is one that is produced by properly functioning faculties in the appropriate environment according to a design plan aimed at truth. Like Sosa, Plantinga makes faculties the focus of analysis, but unlike Sosa he does not identify faculties as virtues because of their consequences. So Plantinga's theory is not modelled on consequentialist ethics, but it is not modelled on virtue ethics either. In fact, Plantinga never uses the term 'virtue' nor does he give any attention to the rich history of the concept of virtue as used in ethics. Plantinga's theory moves closer to traditional accounts of virtue, however, because what counts as properly functioning faculties is determined by a background notion of what is good or desirable for human beings with the nature that they have.

John Greco's version of virtue epistemology modifies Sosa's theory by adding an element that is intended to capture the idea of epistemically responsible as well as reliable belief. To have 'positive epistemic status', Greco says (1990, 1993), not only must a belief be the result of a reliable cognitive faculty (a virtue), but that virtue must have its basis in the believer's conforming to epistemic norms they countenance. Greco's and Sosa's additions of an internalist requirement of belief formation to the reliability condition give their versions of virtue epistemology an ethical component which is missing from simple reliabilism and Plantinga's theory.

Two of the first attempts to link epistemological inquiry with intellectual virtues in the traditional sense of virtue were made by Lorraine Code and James Montmarquet. Code (1987) gives an account of intellectual virtue that 'socializes' epistemology, stresses the place of the knowing subject in the epistemic community, and contextualizes the state of knowing within a background of states that include the non-cognitive (see Feminist epistemology §2-3). She calls her position 'responsibilism' rather than reliabilism because of the knower's degree of choice in cognitive structuring and degree of accountability for these choices. Code does not offer a detailed account of the concept of intellectual virtue, but she is perhaps the first in contemporary epistemology to call attention to the way intellectual virtues in the sense of virtue used in ethics can be useful to the interests of

epistemology.

James Montmarquet (1993) gives an extensive treatment of epistemic virtues in the classical sense of a trait for which we are responsible and which are similar to moral virtues. Montmarquet includes in his list of epistemic virtues such traits as open-mindedness; intellectual carefulness, thoroughness, and impartiality; and intellectual courage and perseverance. He maintains that epistemic virtues are the traits which people who desire the truth would desire to have, but he denies that they are reliably truth-conducive in any straightforward way. So Montmarquet's theory, like Code's, does not evolve out of reliabilism, and his principal concerns are somewhat different from those driving reliabilism.

Linda Zagzebski (1996) has developed a version of virtue epistemology that is explicitly modelled on virtue ethics. Like Code and Montmarquet, what she means by intellectual virtues are such traits as intellectual autonomy and courage, intellectual carefulness and thoroughness, open-mindedness and fair-mindedness, but like Sosa and Greco, she regards reliability as a component of virtue. Zagzebski offers a virtue theory of ethics inclusive enough to handle the intellectual as well as the moral virtues within a single theory, proposing that moral and intellectual virtues have the same basic structure and are acquired in the same way. Both include a motivational component and a component of reliable success in bringing about the aims of the motivational component. In the case of the intellectual virtues this means that reliability in acquiring the truth is a component of intellectual virtue, but there is also a component of intellectual motivation from which the cognitive behaviour characteristic of intellectually virtuous persons arises. Zagzebski then defines the concepts of justified belief and epistemic duty in terms of intellectual virtue in the same way the concepts of right act and of moral duty can be defined in terms of moral virtue in a pure virtue ethics. In both cases the concept of virtue is more basic. She subsequently defines an 'act of virtue', the concept of an act that is praiseworthy in every way - in the act itself, in its motive, in the end it achieves, and which reaches its end because of these other praiseworthy features of the act. An act of intellectual virtue is an act that has an intellectually virtuous motive, is an act that would be characteristically performed by intellectually virtuous persons in the same circumstances, and which reaches truth because of these other features of the act. Knowledge is belief arising out of acts of intellectual virtue. This strategy captures the combination of internal responsibility and epistemic success desired by virtue epistemologists.

3 Advantages and disadvantages of virtue epistemology

When Sosa introduced the concept of intellectual virtue into the contemporary literature, he thought that the shift of focus from properties of beliefs to properties of persons should make it possible to bypass the dispute between foundationalists and coherentists over the logical and evidential relations between beliefs needed for proper epistemic structure. In addition, two possible advantages of reliabilism have already been mentioned. First, its requirements for knowledge are easier to satisfy than internalist theories and, hence, it is said to be closer to common sense than are internalist theories. Second, its requirements for knowledge do not include the possession by the knower of an answer to the sceptical challenge. For example, they need not be able to answer the question 'But what if there is an evil demon?', even though the presence of an evil demon would deprive them of knowledge. Since having an answer to this question is usually thought to be at best difficult, and probably impossible for the average knower, it is an advantage of a theory of knowledge if its formulation permits us to ignore such worries (see Scepticism).

These advantages of reliabilism may be offset by certain disadvantages, however. Consider first the requirement that reliability is a necessary condition for knowledge. Most versions of virtue epistemology have this requirement. A common objection to the reliability requirement for knowledge or justification is the so-called 'generality problem'. This is the problem that a particular belief can be described as an instance of many different belief-forming processes, some broader (believing whatever you read), some narrower (believing what you read in a particular journal), some so narrow as to apply only to a single belief (believing what you read in a certain journal on a certain subject by a certain writer). The degree of truth-conduciveness will vary greatly, depending upon the way in which the belief-forming process is described. This problem requires refinements to the theory rather than outright rejection. Ways of handling the generality problem have been suggested by Goldman (1986), Greco (1993), Sosa (1991) and Zagzebski (1996). Zagzebski suggests that the class of cases against which truth-conduciveness is to be measured should be empirically determined by the way in which people naturally generalize their belief-forming processes. So if a person who believes what they read in a reliable journal then

goes on to believe whatever they read in any periodical, their belief would not count as deriving from a reliable belief-forming process, whereas it would be reliable if they do not tend to generalize their belief-forming tendency to unreliable sources.

Simple reliabilism maintains that reliability is not only necessary, but is sufficient for knowledge. Zagzebski denies that simple reliabilism ought to be considered a form of virtue epistemology, but it is worth mentioning the most serious objection to it since reflection on it was one of the motivations leading to the development of virtue epistemology. The problem is that simple reliabilism does not rule out of the category of knowledge beliefs formed by processes or faculties that are reliable by accident (Plantinga 1993a; Zagzebski 1996). This suggests that any theory that includes reliability as a requirement for knowledge should include an account of what makes a process, trait or faculty reliable in the right way. Virtue epistemologists, then, characteristically add requirements for knowledge other than reliability to eliminate this problem by showing how reliability arises out of something else - in the case of Sosa, the believer’s inner nature; in the case of Plantinga, faculties whose proper function is determined by design; for Greco, the norms the believer countenances; for Zagzebski, intellectual virtues. These conditions involve activity on the part of the knower that exhibits epistemic responsibility or features praiseworthy from an internal perspective.

Requirements for knowledge in addition to reliability are seen by their adherents as improving upon simple reliabilism, but these requirements can also be perceived as detracting from one of the advantages of simple reliabilism. This is its generosity in spreading the domain of knowledge to include true beliefs formed in typical circumstances by young children and unreflective adults. But the more we add responsibility and internal awareness to the conditions for knowledge, the more we shrink the resulting class of knowing states. Can children and unreflective adults have perceptual and memory knowledge on these more demanding theories? Sosa’s way of handling the problem is to distinguish animal knowledge from reflective knowledge. Zagzebski prefers not to make it a condition for knowledge that the believer actually possesses the full virtue but, rather, that the believer has virtuous intellectual motivations and acts cognitively the way virtuous persons do in the same circumstances. Given that virtuous persons formulate perceptual and memory beliefs in many circumstances with little or no reflection or investigation, it is not difficult for children to imitate their behaviour and, hence, to have knowledge in these cases. Greco’s way of handling the problem (1990) is to say that while a belief has positive epistemic status only if it conforms with the norms that the believer countenances, this does not require that the believer should have cognitive access either to the norms themselves or to the fact that their beliefs conform with them.

It can be argued that virtue epistemology has the potential to deal effectively with two other problems of contemporary epistemology. First, there are the problems surrounding the concept of justification which have led to the impasse between internalism and externalism. Since justification is a property of a belief, it is very difficult to adjudicate disputes over this concept if the belief is treated as the bottom-level object of evaluation. If we focus instead on the deeper concept of an intellectual virtue and treat the justifiability of a belief as derivative, it may turn out that justifiability is only one normative property of beliefs among others and the competing intuitions of internalists and externalists require the analysis of more than one property of beliefs, all of which are based in some way on the concept of virtue. Second, focusing epistemology on belief has led to the neglect of two epistemic values that have been important for long periods in the past - understanding and wisdom. An approach focused on intellectual virtues, on the other hand, naturally leads to an account of these values, since understanding and wisdom are either virtues themselves or are very closely connected with virtues (see Wisdom).

Virtue ethics

Virtue ethics has its origin in the ancient world, particularly in the writings of Plato and Aristotle. It has been revived following an article by G.E.M. Anscombe critical of modern ethics and advocating a return to the virtues.

Some have argued that virtue ethics constitutes a third option in moral theory additional to utilitarianism and Kantianism. Utilitarians and Kantians have responded vigorously, plausibly claiming that their views already incorporate many of the theses allegedly peculiar to virtue ethics.

Virtue theory*, the study of notions, such as character, related to the virtues, has led to the recultivation of barren areas. These include: What is the good life, and what part does virtue play in it? How stringent are the demands of morality? Are moral reasons independent of agents' particular concerns? Is moral rationality universal? Is morality to be captured in a set of rules, or is the sensitivity of a virtuous person central in ethics?*

From virtue ethics, and the virtue theory of which it is a part, have emerged answers to these questions at once rooted in ancient views and yet distinctively modern.

1 Aristotle and ancient virtue ethics

Modern virtue ethicists often claim Aristotle as an ancestor. Aristotle, however, was himself working through an agenda laid down by Plato and Socrates. Socrates asked the question at the heart of Greek ethics: 'How should one live?' All three of these philosophers believed that the answer to this question is, 'Virtuously' (see Virtues and vices §§1-3).

The ancient philosophical task was to show how living virtuously would be best for the virtuous person. Plato's *Republic* attempts to answer Thrasymachus' challenge that rational people will aim to get the most pleasure, honour and power for themselves. His argument is that justice, broadly construed, is to be identified with a rational ordering of one's soul. Once one sees that one identifies oneself with one's reason, one will realize that being just is in fact best for oneself. Thrasymachus, of course, might respond that he identifies himself with his desires.

Aristotle continued the same project, aiming to show that human *eudaimonia*, happiness, consists in the exercise (not the mere possession of) the virtues (see Eudaimonia; Happiness). The linchpin of his case is his 'function' argument that human nature is perfected through virtue, a standard objection to which is that it confuses the notions of a good man and the good for man. Ultimately, Aristotle's method is similar to Plato's. Much of *Nicomachean Ethics* is taken up with portraits of the virtuous man intended to attract one to a life such as his.

For Aristotle, all of the 'practical' virtues will be possessed by the truly virtuous person, the man of 'practical wisdom' (Aristotle's central 'intellectual' virtue). Socrates believed that virtue was a *unity*, that it consisted in knowledge alone. Aristotle's position is one of *reciprocity*: the possession of one virtue implies the possession of all. At this point he joined Socrates and Plato in their opposition to Greek 'common sense'. This opposition to common sense is not something that characterizes modern virtue ethics.

2 Modern virtue theory

Virtue theory is that general area of philosophical inquiry concerned with or related to the virtues. It includes *virtue ethics*, a theory about how we should act or live. This distinction is a rough one, but it is important to grasp that much of modern virtue theory is by writers not themselves advocating virtue ethics.

Virtue theory has undergone a resurgence since G.E.M. Anscombe's article 'Modern Moral Philosophy' (1958) (see Anscombe, G.E.M. §2). Anscombe believed that it was a mistake to seek a foundation for a morality grounded in legalistic notions such as 'obligation' or 'duty' in the context of general disbelief in the existence of a divine lawgiver as the source of such obligation (see Duty). She recommended that philosophy of psychology should take the place of moral philosophy, until adequate accounts of such central notions as action and intention were available. Then, she suggested, philosophers might return to moral philosophy through an ethics of virtue.

What is virtue ethics? It is tempting to characterize it as a theory advocating acting virtuously, but this is insufficiently precise. Virtue ethics is usually seen as an alternative to utilitarianism or consequentialism in general

(see Consequentialism; Utilitarianism). To put it roughly, utilitarianism says that we should maximize human welfare or utility. A utilitarian, however, may advocate acting virtuously for reasons of utility. Ethical theories are best understood in terms not of what acts they require, but of the reasons offered for acting in whatever way is in fact required.

Which properties of actions, then, according to virtue ethics, constitute our reason for doing them? The properties of kindness, courage and so on. It is worth noting that there is a difference between acting virtuously and doing a virtuous action. One's doing a virtuous action may be seen as doing the action a virtuous person would do in those circumstances, though one may not oneself be a virtuous person. Virtue ethics, then, concerns itself not only with isolated actions but with the character of the agent. There are reasons for doing certain things (such as kind things), and also for being a certain type of person (a kind person).

This account of virtue ethics enables us to distinguish it from its other main opponent, deontology or Kantianism (see Deontological ethics; Kant, I. §§9-10; Kantian ethics). A Kantian, for example, might claim that my reason for telling the truth is that to do so would be in accordance with the categorical imperative. That is a property of the action of telling the truth quite different from its being honest.

3 The good of the agent and the demandingness of morality

A pure form of virtue ethics will suggest that virtuous properties - 'thick' properties as opposed to thin properties such as 'rightness' and 'goodness' - of actions constitute our only reasons for performing them. Aristotle came close to this position, but it is perhaps more plausible to interpret him as claiming that the rationality of virtue lies in its promotion of the agent's *eudaimonia*. Aristotle's view is nevertheless radical. Since my *eudaimonia* consists only in the exercise of the virtues, I have no reason to live a non-virtuous life.

More common than pure forms of virtue ethics are pluralistic views according to which there are other reason-constituting properties, some perhaps of the kind advocated by utilitarians and Kantians. The open-mindedness of virtue ethics contrasts sharply at this point with what Bernard Williams (1985) has identified as the peculiar narrowness of focus in modern ethics (see Williams, B.A.O.). Considerations other than the moral are relevant to the question of how one should live. Modern virtue ethicists can thus adopt a position on the demandingness of morality between the extremes of Aristotle and their modern opponents. For they need claim neither that self-interest is constituted entirely by being moral nor that morality completely overrides self-interest.

Much of virtue theory has been concerned to develop Williams' criticism of utilitarianism and Kantianism that through their impersonality and impartiality, utilitarianism and Kantianism violate the *integrity* of moral agents. Philippa Foot has developed these critical arguments in a direction favourable to virtue ethics. According to both the principle of utility and the Kantian categorical imperative, moral reasons, being universal, are independent of the desires of agents. Foot (1978), impressed by the rationality of fulfilling one's own desires, has argued that moral reasons do depend on the desires of the agent, so that a person who acts consistently ungenerously may be described as ungenerous, but not necessarily as having any reason to act generously, unless they have a desire which would thereby be fulfilled. Foot is here expressing a doubt similar to Anscombe's about the possibility of ungrounded 'ought' judgments.

4 Agency and motivation

Imagine that you are thanking a friend for visiting you in hospital. She replies, 'Oh, it was nothing. It was obvious that morality required me to come.' This case, taken from an influential article by Michael Stocker (1976), and related to the discussion in the previous section concerning the demandingness of morality and the pervasiveness of the moral point of view, serves to illustrate an ideal of agency which lies implicit in much modern ethical theory (see Moral motivation; Moral realism). The unattractiveness of this ideal can be avoided by utilitarians, who may argue that thinking in the way your friend did about morality is likely to be self-defeating in utilitarian terms. Even the utilitarians, however, can be charged with missing the point. What is wrong with your friend is not that moral thinking like hers fails to maximize utility. Nevertheless, the case constitutes a far more serious problem for Kantians, given Kant's insistence on the explicit testing of courses of action using the categorical imperative, and his view that the moral worth of an action lies entirely in its being done out of a sense of duty.

Modern virtue ethicists such as Lawrence Blum (1980) have endeavoured to replace this conception of moral

agency with a virtue-centred ideal allowing agents to be moved directly by emotional concern for others. This ideal can once again be seen as emerging from Anscombe's attack on the notion of duty. A morality of duty is said to pay insufficient attention to the inner life: the dutiful agent is not doing, or feeling, enough (this criticism is an interesting counterpoint to the accusation that Kantianism is excessively demanding). The charge, then, is not only that modern moral theory fails to provide plausible justifying reasons for action, but that the motivational structure of what is clearly moral agency is quite different from what the theories lead us to expect. Moral agency consists at least partly in acting and feeling in ways prompted by bonds of partiality, requiring no further backing from impersonal ethical theory (see Friendship §4).

5 Universality and tradition

We have already seen how some virtue theorists link moral reasons to motivation. This is one route to a narrowing of the scope of moral reasons. Without any motivation to do so, there is no reason, say, to maximize utility or respect the moral law. Another route is followed by writers such as Alasdair MacIntyre who ground moral rationality in traditions.

MacIntyre's critique of modern ethical theory, outlined in *After Virtue* (1981), is the most stringent in virtue theory. He claims that present moral discussion is literal nonsense: we unreflectively use a mix of concepts left over from moribund traditions; since these traditions are incommensurable, arguments using concepts from rival traditions are irresoluble and interminable. MacIntyre does not, however, follow through the implications of this critique into a Nietzschean moral scepticism, advocating instead a return to Aristotelian virtue ethics (see Nietzsche, F.). The question of how he accomplishes this is an example of a puzzle about virtue theory present since Anscombe's original article: after the sustained critique of modern ethical theory by virtue theorists, is the remaining conceptual apparatus sufficiently strong to support an alternative prescriptive ethics?

The relationship between modern virtue ethicists and Aristotle is complex. Most virtue ethicists, including Foot and MacIntyre, combine an Aristotelian emphasis on the virtues with a modern scepticism about the possibility of an objective theory of the good for an individual. Likewise, MacIntyre's stress on the importance of context is quite Aristotelian, but the relativism to which this leads him would be anathema to Aristotle (see Moral relativism). MacIntyre claims that goods are internal to practices, and not assessable from some external point of view, while Aristotle believed that teleological reflection on universal human nature enabled one to identify those practices which are good *haplōs*, 'simply good'.

The relativism of modern virtue ethics has emerged also in political theory in the debate between communitarians, such as MacIntyre, and liberals (see Community and communitarianism; Liberalism). Along with a predilection for virtue-centred over rule-centred ethics go preferences for the local and particular to the universal, the specific to the general, the embedded to the abstracted, the communal to the individual, the inexplicit to the explicit, the traditional to the revised, the partial to the impartial. In MacIntyre's work, the notion of goods internal to diachronic practices and grounded in traditions is tied to a criticism of a free-floating liberal self, choosing goods from some Archimedean standpoint. MacIntyre's narrative conception of a self opens another door for the readmittance of the notion of character into moral philosophy.

The most serious problem for relativism has yet to be resolved in modern virtue ethics. What are we to say of practices and ways of life constituting internally coherent traditions, yet containing undeniably evil components?

6 Practical reason

One reason for the fading of the notion of character in ethical theory is that utilitarianism and Kantianism have commonly been developed as ethics of rules to resolve dilemmas. An argument against a rule-based ethics is found in Aristotle's discussion of the legal virtue of *epieikeia*, 'equity'. Rules will always run out in hard cases, and some sensitivity is required on the part of the judge to fill the gap between the law and the world. Likewise, for Aristotle, the virtuous man possesses *phronēsis*, 'practical wisdom', a sensitivity to the morally salient features of particular situations which goes beyond an ability to apply explicit rules.

This view has been revived in virtue ethics, by among others Iris Murdoch (1970) and John McDowell, in his article, 'Virtue and Reason' (1979). McDowell argues that we cannot postulate a world as seen by both the virtuous and the unvirtuous, and then explain the moral agency of the virtuous through their possessing some

special desire. Since moral rules run out, any object of desire could not be made explicit. McDowell uses Wittgenstein to support his claim that rational action does not have to be rule-governed (see Wittgenstein, L. §§10-12). This has clear implications for moral education: it should consist in enabling the person to see sensitively, not (or at least not only) in inculcating rigid and absolute principles. This is one of the strands in the feminist critique of modern ethical theory, itself closely tied to virtue theory. Writers such as Carol Gilligan (1982) argue that the moral sensibility of women is less rule-governed than that of men, and this has influenced the 'ethics of care' of, for example, Nel Noddings (see Feminist ethics §1; Moral education §§1-2).

The emphasis in virtue ethics on non-rational factors in moral motivation sits well with the notion of moral sensitivity. And this latter notion provides another standpoint from which one might criticize the basing of morality on the categorical imperative. As we have seen, Foot claims that immorality is not necessarily irrational, since moral reasons depend on the agent's desires. Writers such as McDowell who depict practical reason as perceptual can also deny that immorality is irrational. The unvirtuous lack not any capacity of the theoretical or calculative intellect, but moral sensitivity. Unlike Foot, however, McDowell would argue that this is in fact a failure to perceive genuine reasons for action independent of the agent's motivations.

Again, in McDowell, we see the pastiche, characteristic of virtue ethics, of ancient and modern: rationality is made to depend on social practice, and yet, as Socrates thought, virtue turns out to be a kind of knowledge.

Virtues and vices

The concept of a virtue can make an important contribution to a philosophical account of ethics, but virtue theory should not be seen as parallel to other 'ethical theories' in trying to provide a guide to action.

Modern accounts of the virtues typically start from Aristotle, but they need to modify his view substantially, with respect to the grounding of the virtues in human nature; the question of what virtues there are; their unity; and their psychological identity as dispositions of the agent. In particular, one must acknowledge the historical variability of what have been counted as virtues.

Aristotle saw vices as failings, but modern opinion must recognize more radical forms of viciousness or evil. It may also need to accept that the good is more intimately connected with its enemies than traditional views have allowed. Virtue theory helps in the discussion of such questions by offering greater resources of psychological realism than other approaches.

1 Virtues and theory

Ethical theories are standardly presented as falling into three basic types, centring respectively on *consequences*, *rights* and *virtues* (see Consequentialism; Deontological ethics; Rights; Virtue ethics). One way of understanding this division into three is in terms of what each theory sees, at the most basic level, as bearing ethical value. For the first type of theory, it is *good states of affairs*; for the second, it is *right action*; while virtue theory puts most emphasis on the idea of a *good person*, someone who could be described also as an ethically admirable person. The last is an important emphasis, and the notion of a virtue is important in ethics; but its importance cannot be caught in this way, as the focus of a theory which is supposedly parallel to these other types of theory. Consequentialist and rights theories aim to systematize our principles or rules of action in ways that will, supposedly, help us to see what to do or to recommend in particular cases. A theory of the virtues cannot claim to do this: the theory itself says that what one needs in order to do and recommend the right things are virtues, not a theory about virtues. Moreover, the thoughts of a virtuous person do not consist entirely, or even mainly, of thoughts about virtues or about paradigms of virtuous people. Indeed, they will sometimes be thoughts about rights or good consequences, and this makes it clear that thoughts about the good person cannot displace these other ethical concepts, since a good person will have to use some such concepts. 'Virtue theory' cannot be on the same level as the other types of theory.

An emphasis on virtues is important to moral philosophy for other reasons. Although it need not exclude cognitivism, it shifts attention from morality as a system of propositions or truths to its psychological (and hence, eventually, social) embodiment in individual dispositions of action, thought and emotional reaction. It draws attention to the variety of reasons for action and judgment that may play a part in ethical life, beyond the theorists' favourites, duty and utility (see Moral motivation §§1-3; Morality and identity §4; Morality and emotions). Such reasons will not typically embody virtue concepts themselves, or, still less, involve reflection on the agent's own virtues. But virtue theory can help to explain how considerations such as 'she needs it', for instance, or 'he relied on what you said', can function as an agent's reasons. An approach through the virtues also leaves room for the important idea that ethically correct action may be only partly codifiable and may involve an essential appeal to judgment (see Moral judgment §4; Universalism in ethics §3).

2 Beyond Aristotle: ground; content

The first systematic investigation of the virtues was made by Plato, in such works as *Gorgias* and the *Republic*, and it was extremely significant, for instance in setting the problem of the unity of the virtues (see §3). Plato also posed in a particularly challenging form questions about the value of virtues to their possessor. The classical account of the virtues, however, to which all modern treatments refer, is that of Aristotle (*Nicomachean Ethics*) (see Aristotle §22-5). Just because of the power and the influence of this account, it is easy to underestimate the extent to which a modern theory needs to distance itself from Aristotle. A modern account is likely to agree with Aristotle that virtues are dispositions of character, acquired by ethical training, displayed not just in action but in patterns of emotional reaction. It will agree, too, that virtues are not rigid habits, but are flexible under the application of practical reason. But there are at least four matters on which it is likely to disagree with Aristotle,

which may be labelled *ground*; *content*; *unity*; and *reality*.

Ground. Aristotle held that the virtues (for which the word in his language means only ‘excellences’ - see Aretē) had a teleological ground, in the sense that they represented the fullest development of a certain kind of natural creature, a nondefective male human being. No one now is going to agree with Aristotle that there are creatures who are biologically human beings but who are excluded from this full development by their nature as women or as ‘natural slaves’. Having abandoned his views about women and slaves, modern thinkers face the harder question of how far they agree with Aristotle about the natural basis of the virtues. This in turn raises the question of how strongly Aristotle’s own teleological view should be taken. On one interpretation, he had a comprehensive functional conception of the contents of the universe, with each kind of creature fitting into a discoverable overall pattern. On such a conception, substantial parts of the theory of the virtues will be discoverable by top-down systematic inquiry which will tell us what sorts of creatures human beings are, and hence what their best life will be (see Perfectionism; Teleological ethics). Other interpreters give a more moderate account of Aristotle’s enterprise, according to which his intentions will be honoured by a hermeneutical inquiry into what we, now, regard as the most basic and valuable aspects of human beings.

Content. What is undeniably lacking from Aristotle’s thought, as from that of other ancient thinkers, is an historical dimension. Some modern virtue theorists share this weakness. Aristotle’s account is in several respects different from any account of the virtues one would give now, with respect both to what it puts in and what it leaves out. He gives a particularly important place to a quality called *megalopsuchia*, ‘greatness of soul’, which has a lot to do with a grand social manner and which bears even less relation to a contemporary ethic than its name, in itself, might suggest. A modern person, asked for the principal virtues, might well mention kindness and fairness. Fairness bears a relation to an important Aristotelian virtue, justice, but the latter is defined to an important extent in political and civic terms, and gives a fairly restricted account of fairness as a personal characteristic. Kindness is not an Aristotelian virtue at all. Moreover, there is no account of an important modern virtue, truthfulness; what Aristotle calls the virtue of truth is (surprisingly, as it seems to us) concerned exclusively with boasting and modesty.

There has been obvious historical variation in what is seen as the content of the virtues. Aquinas, who notably developed Aristotle’s account, of course modified it to accommodate Christianity, holding in particular that besides the moral virtues, there were ‘theological’ virtues, which have God as their immediate object (see Theological virtues). The pagans were not in a position to display these, but so far as the moral virtues were concerned, they could be truly virtuous in the light of natural reason. However, there was still something imperfect about their virtue even at this level since, Aquinas held, the whole of ethical life is properly grounded in the virtue called charity, which has a divine origin (see Charity).

For Hume (1751), on the other hand, Aristotle’s account and other pagan sources served to support an ethics of the virtues that was precisely designed to discredit and exclude Christianity (see Hume, D. §4). The historical variation, both in philosophical formulations and in cultural realizations of the virtues, raises wider issues of how theories of the virtues are to be understood. The conceptions of human nature and human circumstances that underlie such theories are open to wide reinterpretation in the face of changing values, and the Aristotelian presupposition that an understanding of human nature could yield a determinate account of the virtues - even if that idea is interpreted relatively unambitiously - looks unrealistic. There are of course constants in the psychology and circumstances of human beings that make certain virtues, in some version or other, ubiquitous: in every society people need (something like) courage, (something like) self-control with regard to anger and sexual desire, and some version of prudence. These platitudes, which are stressed by those who look to a substantive universal virtue theory, severely underdetermine the content of such a theory. This is shown by the very simple consideration that the constant features of human life are indeed constant, but the virtues that have been recognized at different times and by different cultures vary considerably.

3 Beyond Aristotle (continued): unity; reality

Unity. Aristotle inherited from Plato, and ultimately from Socrates, an interest in the unity of the virtues (see Socrates §5). Socrates seems to have held that there was basically only one virtue, which he called wisdom or knowledge. The conventional distinctions between the various virtues - justice, self-control, courage and the rest - were taken to mark only different fields of application of this power. Aristotle did think that there were separate

virtues, but nevertheless his view came almost to the same thing as Socrates', since he thought that one could not have one virtue without having them all. One could not properly possess any one virtue unless one had the intellectual virtue which is called in Aristotle's language *phronēsis* (often translated as 'practical wisdom', but better rendered as 'judgment' or 'good sense'); but, Aristotle held, if one had this quality, then one had all the virtues.

It is not hard to see the general idea underlying this position. Generosity is linked to justice - someone who gives only what justice demands is not being generous. Similar points can be made about the interrelations of some other virtues. However, it is important to the theory of the virtues that they provide psychological explanations as well as normative descriptions, and from a realistic psychological point of view it is hard to deny (as many ancient Greeks other than Socrates and Aristotle agreed) that someone can have some virtues while lacking others. In particular, the so-called 'executive virtues' of courage and self-control can be present without other virtues; indeed, they themselves can surely be deployed in the interests of wicked projects. The refusal to acknowledge this may simply represent an ethical reluctance to give moral accolades to bad people.

The fact that the virtues can, to some degree, be separated from one another itself helps to give point to virtue theory. Some modern ethical theories do imply that there is basically only one moral disposition. Utilitarianism, at least in its direct form, places everything on impartial benevolence (see Utilitarianism; Impartiality); and though Kant himself did have a theory of the virtues, Kantianism insists on the primacy of a sense of duty (see Kant, I. §§9-11; Kantian ethics). An advantage of virtue theory is that it allows for a more complex and realistic account of ethical motivation.

Relatedly, it can acknowledge psychological connections between the ethical and other aspects of character, accepting that people's temperaments have something to do with how they conduct themselves ethically. For the same reason, virtue theory is implicitly opposed to sharp boundaries between the 'moral' and the 'nonmoral', and is likely to acknowledge that there is a spectrum of desirable characteristics, and that no firm or helpful line can be drawn round those that are specifically of moral significance. Aristotle did not even try to draw such a line: his own terminology distinguishes only between excellences of character and intellectual excellences, and one of the latter, *phronēsis*, is itself necessary to the excellences of character. Hume, who, unlike Aristotle, was surrounded by moralists who wanted to draw such a line, goes out of his way to mock the attempt to draw it, and his deliberately offensive treatment of the subject is still very instructive.

Reality. Aristotle conceived of the virtues as objective dispositional characteristics of people which they possess in at least as robust a sense as that in which a magnet possesses the power to attract metals, though people, unlike magnets, have of course acquired the dispositions - in the way appropriate to such things - by habituation (see Moral education). Modern scepticism, however, to some extent supported by social and cognitive psychology, questions whether we can take such a naïve view of what it is for someone to have a virtue. There are at least two different sources of doubt. One is the extent to which people's reactions depend on situation: it is claimed that they will act in ways that express a given virtue only within a rather narrow range of recognized contexts, and if the usual expectations are suspended or even, in some cases, slightly shifted, may not act in the approved style.

The other doubt concerns ascription. When we understand people's behaviour in terms of virtues and vices, or indeed other concepts of character, we are selecting in a highly interpretative way from their behaviour as we experience it, and the way in which we do this (as, indeed, we understand many other things) is in terms of stereotypes, scripts, or standard images, which may range from crude 'characters' to sophisticated and more individuated outlines constructed with the help of types drawn, often, from fiction. The available range of such images forms part of the shifting history of the virtues. At different times there have been pattern books of virtue and vice, and one of the first was the *Characters* written by Theophrastus, a pupil of Aristotle (see Theophrastus; Examples in ethics).

Even assuming such ideas to be correct, it is not clear exactly to what extent they have a negative impact on virtue theory. Everyone knows that virtues do not express themselves under all circumstances, and also that agents may be very rigid in their ability to understand how a situation is to be seen in terms of virtues. Again, with regard to ascription, it is very important that if it is true that we construct our interpretations of another person's character in terms of a stock of images, it is equally true that the other person does so as well. The point is not so much that there is a gap between the interpreter and the person interpreted, but rather that all of us, as interpreters of

ourselves and of others, use shared materials that have a history. There are lessons in such ideas for ethics generally and for virtue theory, but they need not be entirely sceptical. The points about the situational character of the virtues and about their ascription serve to remind us that an agent's virtues depend in many different ways on their relations to society: not simply in being acquired from society and reinforced or weakened by social forces, but also in the ways in which they are constructed from socially shared materials.

4 Vices, failings and evil

Aristotle named a variety of vices, each of which was basically constituted by the absence of the restraining or shaping influence of virtue, together with the operation of some natural self-centred motive. Thus cowardice was the disposition, in the absence of courage, to give in to fear; self-indulgence and irascibility the dispositions to give in to bodily pleasure and to anger. In this range of what may be called 'failings', actions that are expressions of vices do have distinctive motives, but those are not in themselves distinctively bad motives: it is rather that natural motives are expressed in ways in which they would not be expressed by a virtuous person. There are other failings in which the agent's motivation is distinctively deplorable, because it is constituted by the exaggeration, parody or perversion of a virtue: an ostentatious disposition to distribute gifts or favours, in place of generosity, or, to take a modern example, sentimentality in place of kindness. Aristotle notices some failings of this type, but, in line with his 'doctrine of the mean', he oversimplifies their psychology under an unexamined category of 'excess'.

A peculiar case, in Aristotle's treatment, is justice. At the level of actions, at least, it might be thought that there were no distinctive motives to injustice; a person can act unjustly from a variety of motives, and indeed Aristotle mentions the possibility that a coward might treat others unjustly, by 'getting an unfair share of safety'. If this is generalized, an unjust person might be understood not as one with some characteristic motive, but rather as one who is simply insensitive to considerations of justice. However, Aristotle does introduce a distinctive motive for injustice - 'greed' or the desire to have more than others. An unjust person, then - as opposed to someone who has some other vice as a result of which he acts unjustly - is, for Aristotle, a particular greedy type, one who might roughly be recognized in modern terms as 'a crook'.

Aristotle also notices another kind of failing or deficiency, a lack of perception or feeling for others, but this is typically registered by him only as an extreme characteristic, lying off the scale of the ethical, in the form of a brutality or beastliness which virtually falls out of the category of the human. The fact that he does not have anything to say about the more domesticated forms of such a failing, very familiar to us, is a corollary to his not recognizing a virtue of kindness.

It follows from Aristotle's holistic and teleological conception of virtue as the fulfilment of the highest human capacities that vices should be basically failings, instances of a lack or an absence. This hardly leaves room for a notion of the *vicious*: the nearest that Aristotle gets to such an idea is the figure of an obsessional and unscrupulous hedonist. We possess, only too obviously, notions of viciousness deeper and more threatening than this. They point to a concept conspicuously lacking from Aristotle (though to a lesser extent, perhaps, lacking from Plato) - the concept of evil (see Evil).

This leads decisively beyond the conception of vices as failings, even very serious failings. Among evil or vicious motivations, a basic type is cruelty, the desire to cause suffering, a disposition which, as Nietzsche pointed out, contrasts markedly with brutality: it has to share, rather than lack, the sensitivity to others' suffering that is displayed by kindness. In the most typical modes of cruelty, agents derive their pleasure from the sense of themselves bringing about the pain or frustration of others, and their cruel behaviour is directly an attempted expression of power. Rather different from this, though close to it, is maliciousness, as it might be called, a motivation in the style of envy, where the desire is merely that other people's happiness should not exist. Persons in this state of mind may be pleased if others come to grief, even though they do not bring it about themselves. Alberich, in Wagner's *Götterdämmerung*, says, 'Hagen, mein Sohn! hasse die Frohen!' - 'hate the happy'; such a hatred can have many expressions, only some of which involve the specifically active pleasures of cruelty.

Sometimes, cruelty may not only share, as it must, the perceptions that kindness uses, but model itself negatively on kindness, calculating what a kind person might want to do, in order to parody or subvert it. It then takes on the character of perversity. This style of reversal can be applied to virtues other than kindness. There is counter-justice, the disposition to frustrate the ends of justice, not simply in one's own interests, or to hurt or

frustrate a particular person whom one hates or envies, but to take pleasure in the frustration of justice as such and the disappointments inflicted on those of good will. At the limit, this can constitute an almost selfless aesthetic of horribleness, one of the less obvious forms that may be taken by the satisfactions of Milton's Satan, with his resolve that evil should be his good.

5 Links between virtue and vice

Unlike the failings recognized by Aristotle, these evil motivations are more than mere negations. It is important, however, that this need not be taken as a metaphysical claim: one need not be committed to a Manichean view (or even the very various compromises with such a view that have been negotiated by orthodox Christianity), to the effect that human nature or the world itself contains some perversely destructive principle (see Manicheism). One might, for instance, hold, as some optimistic programmes of psychotherapy do, that vicious and cruel motivations are, indeed, perversions, produced by a failure of love or other deficiency in the individual's upbringing. This is an encouraging position, inasmuch as it holds out the hope of a world free of such motivations, but it does not think that such motivations, while they exist, are to be understood simply in terms of the lack of a shaping or restraining influence. It would accept that vicious motivations were specially and inventively active.

Other psychological and social views are less hopeful. It is not simply that they see no ground for Utopian hopes that the world could ever be freed from vicious motivations. Some of them detect deeper ways in which virtue, and more generally the good, depend on their opposites. At the most superficial level, there are contemporary versions of the point made in Mandeville's *Fable of the Bees* (1714) (see Mandeville, B. §2): many benefits, including ethical benefits, have come from the development of commercial society, but there is no known way of replacing greed as a means of sustaining it. At another level, there is no doubt that valuable human achievements, for instance in the arts and sciences, have come about only because of a certain indifference to values of justice and benevolence, both at an institutional level and in the lives of those who have brought about these achievements. (Here, as so often, moralists have to face the question whether or not they are relieved that the values which they think should prevail have not always done so.)

At the deepest level, however, it is not a question simply whether nonethical values may often require the neglect or denial of morality, but whether morality itself does not require it. One of the metaphysicians' illusions, Nietzsche said (1886), is 'the belief in opposing values'. In fact, he thought, moral values will always turn out to implicate their opposites - historically (in terms of how new moral values come to exist), socially (in terms of how they sustain themselves), and psychologically (in terms of how they are learned and of how they derive their energy).

Even if we accept the force of the Nietzschean suspicions, this need not damage, but rather encourages, the project of thinking about morality in ways that give an important place to virtues and vices. A theory of virtues, handled in a truthful way, offers better hope of being psychologically realistic than other prominent pictures of the ethical life do. If, further, it extends its realism to the motivations of immorality as well, and does not treat them as mere negations of the moral dispositions, it will better understand morality itself. It will be more successful in this than other theories of morality, which usually pass over in silence the forces that oppose it, or register them simply as objects of moral disapproval, or treat them as the products of a (typically unexplained) cognitive failure.

Vision

Vision is the most studied sense. It is our richest source of information about the external world, providing us with knowledge of the shape, size, distance, colour and luminosity of objects around us. Vision is fast, automatic and achieved without conscious effort; however, the apparent ease with which we see is deceptive. Since Kepler characterized the formation of the retinal image in the early seventeenth century, vision theorists have known that objects do not look the way they appear on the retina. The retinal image is two-dimensional, yet we see three dimensions; the size and shape of the image that an object casts on the retina varies with the distance and perspective of the observer, yet we experience objects as having constant size and shape. The primary task of a theory of vision is to explain how useful information about the external world is recovered from the changing retinal image.

Theories of vision fall roughly into two classes. Indirect *theories characterize the processes underlying visual perception in psychological terms, as, for example, inference from prior data or construction of complex percepts from basic sensory components.* Direct *theories tend to stress the richness of the information available in the retinal image, but, more importantly, they deny that visual processes can be given any correct psychological or mental characterization. Direct theorists, while not denying that the processing underlying vision may be very complex, claim that the complexity is to be explicated merely by reference to non-psychological, neural processes implemented in the brain.*

The most influential recent work in vision treats it as an information-processing task, hence as indirect. Computational models characterize visual processing as the production and decoding of a series of increasingly useful internal representations of the distal scene. These operations are described in computational accounts by precise algorithms. Computer implementations of possible strategies employed by the visual system contribute to our understanding of the problems inherent in complex visual tasks such as edge detection or shape recognition, and make possible the rigorous testing of proposed solutions.

1 Historical background

The fact that the image on the retina does not correspond in an obvious manner to the way things look suggests that some processing of the stimulus occurs in visual perception. Theorists of vision have proposed various accounts of the nature of the processing responsible for our perception of size, shape and distance. *Geometric* models, popular among optic theorists in the seventeenth century, and suggested in some of René Descartes' work on vision (particularly, his Sixth Set of Replies 1641: §9), construe visual processing as a species of mathematical calculation (see Molyneux problem). Geometric models can therefore be seen as precursors of modern-day computational models of vision (see §§4-7 below). According to one geometric model, the visual system computes the distance of an object in the visual field from the angles at which the light from the object strikes each eye, and the distance between the two eyes. The knowledge required for the calculation, including knowledge of the precise angles formed by the eyes when looking at an object, and knowledge of the relevant mathematical theorems, was thought to be provided by innate mechanisms, rather than acquired from experience (see Innate knowledge). A significant defect of geometric models is that they failed to provide an account of how the requisite knowledge is made available to the visual system, or how it is deployed in calculations that were presumed to be unconscious.

The philosopher George Berkeley, in his influential 'Essay Towards a New Theory of Vision' (1709), questioned the psychological reality of the geometric models, arguing in effect that the information upon which the postulated calculations are based is not available to the visual system. Berkeley agreed with the geometric theorists that retinal information alone is insufficient to account for our perception of distance and size, but, consistent with his more general empiricism, he claimed that the process by which we acquire such knowledge is not a species of calculation based on innately specified information, but rather associative and learned.

According to Berkeley, our ideas of distance and size, unlike our ideas of colour, are not really *visual* ideas at all. Whereas light reflected at different wavelengths affects the retina differentially, and so gives rise to different colour sensations, light reflected from different distances does not. There is no characteristic retinal pattern associated with something's being 10 feet away. As Berkeley put it in his famous 'one point' argument, 'distance being a line directed end-wise to the eye it projects only one point in the fund of the eye, which point

remains invariably the same whether the distance is larger or shorter' (1709: §2). Similarly for size: there is no characteristic retinal pattern produced by our looking at an object that is 6 cubic feet in volume. A larger object placed at a greater distance along the line of sight will have the same geometric effect on the retina. Our ideas of distance and size, Berkeley concluded, derive not from visual experience, but from movement and touch; from our tangible acquaintance with objects. We can tell the distance and size of objects by sight only because we learn to associate visual cues, including sensations caused by the convergence of the eyes and the accommodation of the lens, with ideas originally derived from our tangible sense.

Central to Berkeley's account of distance and size perception is the empiricist doctrine that there are no meaningful abstract ideas, that is, ideas not reducible to sensation (see Empiricism; Sense-data). He rejected the possibility that we might possess abstract spatial ideas that are shared by visual and tangible experience (see Molyneux problem). Later theorists of vision who do not share Berkeley's epistemological and metaphysical assumptions have found his claim that our ideas of distance and size are derived from our sense of touch uncompelling; however, his discussion of the phenomena to be explained by a theory of vision shaped the field well into the twentieth century.

2 Direct v. indirect perception

The claim that visual perception is not direct or immediate involves more than the truism that some processing of the retinal image is necessary to account for what we see. Ideas or perceptions are thought not to be 'direct' if they are produced by *psychological* processes. While the notion of a psychological process admits of no precise definition, examples come readily to mind. Any process that occurs in consciousness, such as the association of ideas, is a psychological process, as is any process that involves learning. Mathematical calculation of distance and size based on the prior *representation* of lines and angles, whether accessible to consciousness or not, is a psychological process (see Intentionality). Since Berkeley's theory and the models of the geometric writers both posit psychological processing of the image (albeit of different sorts), they are considered indirect theories of vision.

The difference between direct and indirect accounts of perception has been characterized as a disagreement over the richness of the stimulus, with direct theorists typically arguing that the stimulus contains more information than indirect theorists have been willing to allow. For example, James J. Gibson (1904-79), a prominent direct theorist, claimed that the input to the visual system is not a series of static 'time slices' of the retinal image, but rather, the smooth transformations of the optic array as the subject moves about its environment (what Gibson (1979) called 'retinal flow'). But to characterize the fundamental difference between direct and indirect theories as a disagreement over the richness of the stimulus is to misplace the dispute. The issue that separates the two camps concerns neither the amount of information contained in the stimulus, nor even the precise character of this information, but, rather, how the information in the stimulus is accessed and used by the visual system to produce knowledge that is useful to the organism. In other words, it concerns the character of the intervening processes. Direct theorists deny that visual processes can be characterized in terms of ideas, beliefs, representations, knowledge or memories. In other words, they deny that visual processes have any true psychological description. A direct theory explicates any intervening or supplementary processing that occurs in perception in terms of neural structures and processes directly implemented in the brain. Indirect theorists, of course, do not deny that perceptual processes are implemented in neural structures, but they argue that such processes should be characterized at a distinct, psychological, level of description.

Direct theories of perception are sometimes explicitly contrasted with accounts that treat perception as a species of inference, akin to the drawing of a conclusion from premises according to a principle or rule. The nineteenth-century German physicist and physiologist Hermann von Helmholtz argued that the processes underlying visual perception are of the same general sort as inductive generalization employed in scientific reasoning (see Inductive inference; Inference to the best explanation). The contemporary psychologist Irvin Rock (1983) advances a view that explicitly treats much of perception as a process of hypothesis generation and testing. But the use of 'inferential' as a blanket term to refer to indirect theories of perception is somewhat misleading. The various processes that can be thought of as psychological (for example, conscious inference, unconscious calculation, habit-based association, and so on) seem too heterogeneous a collection to justify characterizing the entire class in terms of the drawing of conclusions from antecedently established premises.

3 Direct theories of vision

The ‘Gestalt’ movement of the early twentieth century rejected the view, prevalent since Berkeley, that complex percepts can be analysed into simple sensory components (see Gestalt psychology). According to the Gestalt theorists, perception is *holistic*: perceptual wholes are not built up out of more basic sensory elements, in the way, for example, that a painting is just the combination of all the paint-covered segments of the canvas. Gestalt theorists claimed further that perception is direct - perceptual processing is not correctly described in terms of psychological or mental processes. The structure of a visual experience is to be explicated in terms of the structure of the underlying brain states, that is, in neurophysiological terms. The Gestalt psychologist Wolfgang Köhler characterized as a *physical gestalt* any dynamic system that settles into an equilibrium state of minimal energy. A soap bubble forming a perfect sphere is an example of a physical gestalt, as is, Köhler argued, the brain producing an organized percept. Köhler proposed a theory that appealed to electrical fields within the brain to account for perception (and all other mental processes). Gestalt speculative physiology was not borne out by subsequent brain research, which failed to discover evidence of Gestalt mechanisms implicated in perceptual processing.

The psychologist James J. Gibson shared with the Gestalt theorists the belief that visual perception is not mediated by processes characterizable in psychological terms. Gibson argued that indirect theorists have mischaracterized the information in the optical array. If the effective stimulus for the visual system is taken to be retinal flow (the smooth transformations of the optic array as we move about), then, according to Gibson, there are important constancies in the stimulus that indirect theorists have typically missed. There is therefore no need to posit inferences, calculations, memories, association of ideas, or any other intervening psychological process, to explain our perception of size and shape constancy. In addition to brightness and colour, properties directly picked up in the stimulus include, according to Gibson, higher-order properties that remain invariant through movement and changes in orientation. These higher-order invariants specify not only structural properties such as ‘being a cube’, but also what Gibson called ‘affordances’, which are functionally significant aspects of the distal scene, like the fact that an object is edible or could be used for cutting.

Two fundamental assumptions underlie Gibson’s ‘ecological optics’: (1) that functionally significant aspects of the environment structure the ambient light in characteristic ways; and (2) that the organism’s visual system has evolved to detect these characteristic structures in the light. Both assumptions are controversial. With respect to (2), indirect theorists have complained that Gibson provides no account of the mechanism that allegedly detects salient higher-order invariants in the optical array. His claim that the visual system ‘resonates’, like a tuning fork, to these properties is little more than a metaphor. But it should be noted that in claiming that perception of higher-order invariants is direct, Gibson is simply advocating that the mechanism be treated as a black box, from the point of view of psychology, because no inferences, calculations, memories or beliefs mediate the processing. (The physiological account of the mechanism’s operation will no doubt be very complex.) This claim might be plausible if assumption (1) is true - if there is a physically specifiable property of the light corresponding to every affordance. But for all but the simplest organisms it seems unlikely that the light is structured in accordance with the organism’s goals and purposes. More likely, the things that appear to afford eating or cutting or fleeing behaviour structure the light in all kinds of different ways. This likelihood has led indirect theorists to claim that something like categorization - specifically, the bringing of an object identified initially by its shape, colour or texture under a further concept - is at work when an organism sees an object *as* food, *as* a cutting implement, or *as* a predator.

4 Computational models of vision: general approach

The predominant theoretical approach in cognitive psychology in recent years has been computationalism, which treats human cognitive processes, including perceptual processes, as a species of information processing (see Mind, computational theories of). Computational theories of vision attempt to specify the aspects of the external world that are represented by the visual system, and to characterize the operations that derive these representations from the information contained in the retinal image.

One of the most prominent early computational vision theorists was David Marr (1945-80), a researcher in the Artificial Intelligence Laboratory at the Massachusetts Institute of Technology. While the details of Marr’s specific computational model have been challenged by later theorists, his work is of continuing interest to philosophers and psychologists concerned with the foundations of the computational approach to vision.

Marr argued in his book *Vision* (1982) that an information-processing capacity can be analysed at three distinct levels of description. The 'theory of the computation' is a precise specification of the function computed by the mechanism, in other words, what the mechanism does. For example, the theory of the computation for a particular device may tell us that it adds numbers, or computes averages when given a list of numbers as input. The *algorithm* specifies the procedure or rule for computing the function, and the *implementation* level describes how the computation is carried out in neural or computer hardware. The first two levels in the hierarchy - the abstract characterization of the problem and the rule for its solution - exemplify a fundamental commitment of the computational approach: that cognitive processes can be understood in a way that is independent of the particular mechanisms that implement them in the brain.

Computational models treat the visual system as computing from the retinal image a representation of the three-dimensional structure of the distal scene. Marr's theory divides this process into three distinct stages, positing at each stage the construction of a representation that makes explicit (some of) the information contained in the image and represents it in a way that is efficient for later use. Various computational processes, some running in parallel, are defined over these representations. The algorithmic level of description characterizes the procedures the visual system uses to produce increasingly more useful representations of the scene.

Most of the processes that Marr describes are *data driven*, or 'bottom up' - they operate on information contained in the image, without supplementation by high-level information or beliefs about the world that the subject may have. These processes use information about intensity changes across the visual field, or the orientation of surfaces, not such facts as that objects of a particular shape typically make good cutting implements. Marr advocated 'squeezing every ounce of information out of the image' before positing the influx of supplementary knowledge.

Data-driven models of perception have a number of advantages over *hypothesis-driven* models which appeal to high-level knowledge very early in visual processing. Data-driven processes are generally faster - the visual system does not have to retrieve the relevant piece of specialized knowledge before processing the information in the image - and tend to be more reliable. In Marr's model, the point at which high-level information is available to the visual system marks a distinction between *early* and *late* vision. Early visual processes are said to be 'cognitively impenetrable' by the subject's beliefs about the world (see Modularity of mind). As a consequence, they cannot be influenced by learning.

Marr emphasized the importance of the 'topmost' level of description - the theory of the computation - in developing accounts of human cognitive capacities. He noted that there is no point attempting to describe how a mechanism works before knowing what it does. A crucial first step in constructing a theory of a perceptual capacity is discovering constraints on the way the world is structured that enable adapted organisms to solve perceptual problems in their normal environments. An example should make the point clear. Marr's student and co-worker Shimon Ullman (1979) has proved that three distinct orthographic views of four non-coplanar points are sufficient to determine the three-dimensional structure of a rigid body (the 'structure from motion' theorem). If a body is not rigid, much more information is required to compute its shape. In a world such as ours, where most things are relatively rigid, a visual system built (that is, adapted) to assume that the objects in its environment are rigid would be able to compute the structure of those objects more easily and quickly than a visual system that had to consider the many non-rigid interpretations consistent with the data. Accordingly, Marr posited a mechanism that given three views of four non-coplanar points as input selects the unique rigid interpretation consistent with the data.

Recall Berkeley's objection to the geometric theorists' accounts of size and distance perception. He claimed that the information required for the postulated calculations was not generally available to the visual system, nor to the organism. Such a criticism, if true, is devastating for a computational account of a cognitive capacity. Any computational theory that posits processing beyond the computing capabilities of the mechanism, or that relies on information unavailable to the mechanism, is a non-starter as a biological model. An important lesson of Marr's work is that the theorist must attend to the structure of the organism's environment before attempting to characterize computational mechanisms, because the environment determines the nature of the computational problems that the organism's visual system needs to solve. The perceptual systems of adapted organisms can be assumed to 'exploit' very general information about the environment. Consequently, the problems they have to

solve may be simpler and computationally more tractable than might initially be assumed.

5 Computational models of vision: modularity

Another characteristic feature of Marr's theory is that it treats the visual system as comprising a number of individual components or modules that can be analysed independently of the rest of the system. A 'module' is, by definition, cognitively impenetrable: its operation is not influenced by information external to it that may be available to the cognitive system as a whole, for example, information in the system's memory (see Modularity of mind). Marr posited a module responsible for computing three-dimensional structure from apparent motion, another for computing depth from disparity information available in stereo images, a third for computing shape from shading. Each of these modules is designed to exploit general environmental constraints in the manner that the 'structure from motion' module, described above, incorporates the rigidity assumption.

The various modules operate in parallel, and since they yield information about the depth of the distal scene from different input data, they may give inconsistent results. This is an advantage for the organism, because in cases where the general environmental constraints assumed by a processing module do not hold, the output of the module is subject to correction by another module operating on different data, and exploiting different environmental constraints. For example, imagine a non-rigid mass of jelly moving through space. Since the 'structure from motion' module is built to assume rigidity it will probably give an incorrect interpretation of the jelly's structure. But its output is then likely to be inconsistent with, and correctable by, the output of modules operating on shading or disparity information, which, though they exploit other environmental constraints, do not assume rigidity.

The principle of modular design has an evolutionary rationale. Modular processes are typically fast, because a time-consuming search of general memory is avoided. And assuming that the constraints governing a module's operation are generally true, the process will normally be reliable. Commitment to the principle of modular design makes the computational theorist's job easier, since modular processes can be studied and modelled without the theorist knowing how more central reasoning systems work. For all their theoretical advantages, however, modules do pose a general problem. The theorist has to explain how the outputs of various modular processes are combined in a single representation of the structure of the scene. The possibility of inconsistent results from different modules suggests that this is a non-trivial problem.

In general, then, the visual processes posited in Marr's theory have three important features. They are data-driven, adapted to exploit general environmental constraints, and modular. The visual system, according to Marr, computes a series of intermediate representations of distal information, culminating in a representation of the three-dimensional structure of the scene. The input to the system is the image on the retina, in effect, a grey-level intensity array. The initial processing of the image produces what Marr called the 'primal sketch', a representation of the way that light intensities change over the visual field. The primal sketch makes explicit precisely the information that is required for subsequent processing. Discontinuities in intensity tend to be correlated with significant features of the scene, that is, object boundaries, although it is too early at this stage to assume that all sharp intensity changes in the image indicate edges in the world. Some may be produced by changes in illumination or surface reflectance (see Colour and qualia).

The various processing modules described above operate on aspects of the information contained in the primal sketch. The results are encoded in a representation that Marr called the '2.5-dimensional sketch'. It makes explicit the depth and surface orientation of the scene, and is the input representation for later visual processing. The visual system is assumed to be cognitively impenetrable up to the production of the 2.5-dimensional sketch, hence its operation to this point cannot be influenced by learning.

6 Computational models of vision: object recognition

Late or high-level visual processes use the representations of depth and surface orientation produced by early vision for tasks such as object recognition, locomotion and visually guided manipulation. Marr's own account of late visual processing is rather sketchy. His concrete proposals concern the computational level of description, with little or no detail supplied at the algorithmic level. In general, computational models of high-level vision are not as well developed as accounts of early visual processes. The difficulty is due in part to the fact that later

processing is hypothesis- (or goal-)driven, and hence cognitively penetrable. The input to these processes is not limited to information contained in the image. Object recognition, for example, makes use of specific knowledge about objects in the world. This knowledge is usually characterized as a catalogue of object types stored in long-term memory. It is worth noting that only at this rather late stage does the visual system do anything like identify what Gibson calls ‘affordances’, and in computational accounts such identification is typically treated as a process of categorization, in other words, as a psychological process (see Concepts §1).

Various types of computational models of object recognition have been proposed. According to the simplest models, recognizing an object currently in view involves comparing it with previously stored views of objects and selecting the one that most resembles it. A problem with this approach is that it fails to explain our ability to recognize objects from novel views that do not straightforwardly resemble any previously stored views.

More promising are accounts that treat object recognition as associating with the current view of the object a description of the object type, perhaps in addition to previously stored views of representative examples. Here again, different approaches are possible. ‘Invariant-property’ accounts assume that the set of possible retinal projections of objects typically have higher-level invariant properties that are preserved across the various transformations that the object may undergo. Such proposals face the same problem as Gibson’s account of higher-order invariants. For most object types it has proved impossible to find specifiable properties of the image that are common to all possible recognizable views.

The ‘decomposition’ approach to object recognition maintains that objects are identified on the basis of prior recognition of their component parts. An assumption of this approach is that the relevant part-whole relations are invariant and detectable in all possible views where the subject would recognize the object. The most developed proposal is Irving Biederman’s ‘recognition by components’ theory (1990), according to which a given view of an object can be represented as an arrangement of simple primitive volumes called ‘geons’ (for ‘geometric icons’). Geons can themselves be characterized in terms of viewpoint-invariant properties, and, proponents of the theory claim, are recognizable even in the presence of visual noise. In general, though, the decomposition approach to object recognition has proved to be fairly limited in its application. Many objects do not decompose in a natural way into easily characterizable parts; and for many of those that do the decomposition is insufficient to specify the object in question.

A third strategy, known as the ‘alignment’ approach, suggests that the visual system detects the presence of transformations between the current view of an object and a stored model, and can ‘undo’ the transformation to achieve a correspondence between the two. For example, suppose that the current view of the object differs from the model stored in memory because the object has undergone a three-dimensional rotation and moved further away from the viewer. On the current proposal, the visual system first detects the nature of the transformations, and then performs them in reverse on the current view to bring it into ‘alignment’ with the stored model (assuming that the object is rigid). The main problem for this approach, as for the other proposals, is its limited applicability. It is only feasible for a small range of possible transformations that an object can undergo (for example, rotation and scaling) and then only for a limited range of objects. (Imagine detecting and ‘undoing’ the rotation of a crumpled piece of newspaper.)

‘Mixed’ approaches to object recognition attempt to extend the range of applicability of the decomposition and alignment approaches by combining elements of the two, positing separate identification systems that operate in parallel. While mixed accounts appear promising, they face the additional burden of explaining how the outputs of the two recognition systems are combined.

7 Computational models of vision: problems and prospects

The most common criticism of computational models of human cognitive capacities, including accounts of our perceptual abilities, is that they are unable to approximate actual human performance. It is true that many impressive computer models fail miserably in the real world. Sometimes they fail because the information required is not available to the mechanism. As Marr emphasized, the computational theorist can try to avoid this problem by first attempting to characterize the computational problems that perceptual mechanisms, in their natural context, are required to solve, a process that involves discovering general environmental constraints that perceptual mechanisms of adapted organisms can be expected to exploit.

But the study of biological visual systems faces additional hurdles. Even if the information on which a posited process runs is in some abstract sense ‘in the data’, the input may be too ‘noisy’ for the mechanism to make use of it. Computational theorists are of course aware of this problem. Some of the processing posited by computational accounts, especially in early vision, involves the elimination of extraneous or irrelevant information in the image. (For example, the primal sketch, which represents intensity changes in the image, does not preserve the absolute values of intensity gradients at every point in the grey-level array.) Moreover, the theorist must eventually find neural hardware capable of doing the computationally characterized job, before being confident that the model is biologically feasible. Given the difficult nature of the task it is unlikely that a complete computational account of vision is just around the corner. None the less, computational theorists make an important contribution to our understanding of vision by their careful study of the nature of the problems to be solved by visual mechanisms, although the solutions they offer are properly evaluated by their performance in the real world.

An alternative style of computational model may ultimately prove better suited to explicating human vision than models, such as Marr’s, that treat perceptual processing as rule-governed operations defined over representations. In ‘connectionist’ computational architectures information is typically represented by patterns of activation over a connected network of units or nodes. Connectionist processes are explicated at a level distinct from the neurological or implementational. Connectionist cognitive models typically appeal to representations, memory and learning, hence they qualify as indirect; although connectionist accounts of representation, memory and learning differ in significant respects from more traditional computational accounts (see Connectionism). Connectionist theorists have claimed that their models are better able to handle noisy input and ‘multiple simultaneous constraints’ characteristic of real-world processing situations, though traditional computationalists dispute this claim. Whether the best models of human visual processing will be connectionist remains to be seen.

Vital du Four (*c.*1260-1327)

A Franciscan philosopher and theologian, Vital du Four was noted for denying the distinction between a thing's essence and its existence, for expounding an Augustinian theory of perception and for emphasizing the absolute power and contingency of God's will in creating the universe. One interpretation of his views holds that created things have no intrinsic goodness, only that which has been conferred upon them by God.

Born in Bazas, in the southwest of France, Vital du Four (or Vitalis de Furno) entered the Franciscan order, was educated in theology at Paris in 1285-91, and taught at Montpellier (1292-6) and Toulouse (1296-1307). He was appointed a cardinal in 1312, becoming Cardinal-Bishop of Albano in 1321. He died in 1327 in Avignon. A contemporary of John Duns Scotus, du Four has been so overshadowed by his Franciscan colleague's philosophical accomplishments that until recently, one of du Four's major works, *De rerum principio (On the Origin of Things)*, was erroneously included in Scotus' *Opera omnia*.

Du Four rejected Thomas Aquinas' thesis that, except for the case of God, there is a distinction between an individual's essence and its existence (see Aquinas, T. §9). According to du Four, the existence of any individual (other than God) just is that individual's essence as related to the individual's efficient cause. Du Four's thesis seems to be that for Socrates to exist is for Socrates' essence - namely, to be a rational animal - to stand in a certain relation to whatever is the efficient cause of Socrates. The relation includes the notion of participation: the relevant activity of Socrates' efficient cause results in an individual, Socrates, who participates in the essence of being a rational animal.

Unlike a theory, popularly associated with Aquinas, that maintained that genuine knowledge must be only of universal, necessary truths, du Four allows knowledge to extend to contingent particulars. Knowledge of physical objects comes about through sensation, which apprehends individual things. Du Four claims, however, that sensation itself necessarily involves the simultaneous operation of the intellect, thus precluding any view that maintains that the intellect operates only after it receives the testimony of the senses. While the senses apprehend individuals, the intellect cognizes the activities of the senses along with the individuals that are the objects of those activities. Augustine's theory of 'vital attention' had maintained that sense perception is possible only when the soul actively attends to the events occurring in the body, because the inferior body cannot in itself cause changes in the superior soul (see Augustine). Du Four's account of the intellect's activity in sense perception is reminiscent of Augustine's theory, although it is not clear that du Four subscribes to Augustine's causal principle.

In contrast to the way in which knowledge of contingent particulars is acquired, du Four introduces a theory of divine illumination (an important expression of which could also be found in Augustine's writings) to account for knowledge of necessary, universal truths. Human intellects are too inconstant to grasp such immutable truths by their own natural means. Knowledge of necessary truth is the result of the soul's union with God's light, and the acquisition of such knowledge is entirely dependent on God's will.

Du Four rejects the opinion, expressed in Plato's *Timaeus* (see Plato §16), amplified by Pseudo-Dionysius the Areopagite and expounded afterwards by Avicenna (see Ibn Sina), that creation is a necessary outcome of God's goodness. God is necessarily infinitely good, but the necessity of God's goodness has its source in God's own immutable will and not in any kind of external compulsion. No aspect of creation is sufficient to move God to create. In particular, the goodness of creatures does not enhance God's goodness, and so their goodness is accidental to God's willing to create.

As du Four puts it, creatures add nothing to God's goodness 'just as a point adds nothing to a line' (*De rerum principio* 4.1.3). He may have intended this analogy only to imply that because God is *infinitely* good intrinsically, no extrinsic good can add to God's goodness; but he may also have intended the analogy to convey the thesis that just as points have no length in themselves by which to augment the length of a line, so created beings have no goodness in themselves. On either interpretation, du Four's view stresses the contingency of God's creating: God could have refrained from creating anything, let alone this world. The second interpretation, however, adds the further thesis that the goodness of the created world is not something intrinsic to it, and suggests that if the world is properly to be regarded as good, its goodness must be conferred on it by a declaration of God's free will. Du

Four's analogy may thus have influenced the voluntaristic views of William of Ockham less than a generation later.

Vitalism

Vitalists hold that living organisms are fundamentally different from non-living entities because they contain some non-physical element or are governed by different principles than are inanimate things. In its simplest form, vitalism holds that living entities contain some fluid, or a distinctive 'spirit'. In more sophisticated forms, the vital spirit becomes a substance infusing bodies and giving life to them; or vitalism becomes the view that there is a distinctive organization among living things. Vitalist positions can be traced back to antiquity. Aristotle's explanations of biological phenomena are sometimes thought of as vitalistic, though this is problematic. In the third century BC, the Greek anatomist Galen held that vital spirits are necessary for life. Vitalism is best understood, however, in the context of the emergence of modern science during the sixteenth and seventeenth centuries. Mechanistic explanations of natural phenomena were extended to biological systems by Descartes and his successors. Descartes maintained that animals, and the human body, are 'automata', mechanical devices differing from artificial devices only in their degree of complexity. Vitalism developed as a contrast to this mechanistic view. Over the next three centuries, numerous figures opposed the extension of Cartesian mechanism to biology, arguing that matter could not explain movement, perception, development or life. Vitalism has fallen out of favour, though it had advocates even into the twentieth century. The most notable is Hans Driesch (1867-1941), an eminent embryologist, who explained the life of an organism in terms of the presence of an entelechy*, a substantial entity controlling organic processes. Likewise, the French philosopher Henri Bergson (1874-1948) posited an* élan vital *to overcome the resistance of inert matter in the formation of living bodies.*

1 Experimental physiology

The role of vitalism in physiology is exemplified in the work of the French anatomist Xavier Bichat (1771-1802). Bichat analysed living systems into parts, identifying twenty-one distinct kinds of tissue, and explaining the behaviour of organisms in terms of the properties of these tissues. He characterized the different tissues in terms of their 'vital properties', as forms of 'sensibility' and 'contractility'. Bichat thought the sensibility and contractility of each tissue type constituted the limit to decomposing living matter into its parts. These vital properties preclude identifying life with any physical or chemical phenomenon because the behaviour of living tissues is irregular and contrary to forces exhibited by their inorganic constituents. Insofar as living matter maintains itself in the face of ordinary physical and chemical processes that would destroy it, Bichat thought it could not be explained in terms of those forces. He therefore allowed that there are additional fundamental forces in nature that are on a par with those Newton ascribed to all matter: 'To create the universe God endowed matter with gravity, elasticity, affinity…and furthermore one portion received as its share sensibility and contractility' (Bichat 1801, vol. 1: xxxvii). These are vital properties of living tissues.

The key to explaining the distinctive properties of living systems is showing how those properties stem from the constitution of the system. Bichat traced the properties of living systems back to their components; when this was done, the vital properties assigned to these components were opposed to their physical properties. François Magendie (1783-1855) provides a useful contrast. Many of Magendie's experiments mirrored those of Bichat, but he interpreted them as revealing the different steps in a physiological process. Magendie's avowed goal was to abolish the vital properties known as sensibility and contractility, and to 'consider them as functions' (1809). Magendie rejected a mechanistic account of those functions, and acknowledged that many physiological phenomena remained beyond experimental reach, so that it was not possible to explain them in more basic physical terms. Because he acknowledged this distance between vital functions in living organisms and what it was possible to explain in physical terms at the time, Magendie was construed by many as a vitalist; if he is a vitalist at all, his vitalism is very different from that of Bichat.

2 Physiological chemistry

Inspired by Lavoisier's new analysis of combustion, and his demonstration with Laplace in 1780 that respiration in animals is 'slow combustion', chemists in the early nineteenth century hoped to explain many of the reactions found in living organisms. Organic compounds are apparently formed only in living organisms, and thus appear to be products of vital activity. The physiological chemists of the early nineteenth century set out to show, contrary to initial appearances, that these products *are* the results of chemical processes. Jacob Berzelius (1779-1848) argued

that chemistry could account for all of the reactions occurring within living organisms, and that organic and inorganic processes differ only in complexity. ‘ There is’, he said, ‘no special force exclusively the property of living matter which may be called a vital force’ (1836).

A vitalistic view of the relationship of chemistry to physiology is found in Justus Liebig’s study of chemical reactions in plants and animals (1842). In animals he was particularly interested in reactions which metabolize foodstuffs, separating the constituents needed for growth. Liebig offered detailed chemical analyses of the sequence of reactions, based upon chemical analysis of the foods taken in, the products absorbed, and the waste products released. Liebig saw a need for some form of regulation of these reactions, and posited a vital force controlling them. Chemical and vital processes operate in opposite ways, and consequently both sorts of process are necessary in order to understand metabolism. Liebig’s vital forces were not meant to undermine a mechanist programme; rather, they are forces comparable to other physical forces such as gravity and chemical affinity that are possessed by matter and would be exhibited under appropriate conditions. ‘ There is nothing to prevent us from considering the vital force as a peculiar property, which is possessed by certain material bodies, and becomes sensible when their elementary particles are combined in a certain arrangement or form’ (Liebig 1842). Vital forces were invoked to explain phenomena which would otherwise lack an explanation.

Though Berzelius and Liebig were divided over what vital forces they would tolerate, they were united in the desire to explain activities in living organisms in chemical terms. They thought vital forces were necessary because some phenomena have no adequate chemical explanation. Their position is evident in the stance they took on fermentation: it is a chemical process and should be interpretable in chemical terms, whether it is occurring within living organisms or in the test tube. They viewed fermentation and putrefaction as the least challenging cases for chemists, since both processes are simply processes of decomposition and thus the result of simple chemical activity of the sort found in inorganic cases. With the development of better microscopes, Theodor Schwann (1810-82) observed in 1838 that single-celled organisms (yeasts) are involved in fermentation, setting the stage for a controversy that continued for the rest of the century. Schwann and Louis Pasteur (1822-95) argued that fermentation was an activity of whole living organisms and not reducible to ordinary chemistry. This seemed to be a vitalist position. Schwann, though, advanced a mechanistic theory of cell formation, claiming cells simply constitute special environments in which ordinary matter appears in different concentrations. This is not vitalistic. Pasteur, by contrast, fitted fermentation into a more general programme describing special reactions that only occur in living organisms. These are irreducibly vital phenomena. Pasteur demonstrated empirically in 1858 that fermentation only occurs when living cells are present and, further, that cells only carry out fermentation in the absence of oxygen, leading him to describe fermentation as ‘life without air’. Finding no support for claims such as those advanced by Berzelius, Liebig, Traube and other chemists that fermentation resulted from chemical agents or catalysts within cells, Pasteur concluded that fermentation was a ‘vital action’.

In addition to their apparent success in showing that fermentation only occurs in living cells, vitalists like Pasteur also appealed to their demonstration that living organisms always originate from living organisms and that there is no spontaneous generation. The idea of spontaneous generation was inspired in part by the observation of small organisms forming in putrefying matter. The controversy is rooted in the conflict between John Needham (1713-81) and Lazarro Spallanzani. Needham heated closed vessels of meat-broth, discovering that when cooled they still yielded micro-organisms. Spallanzani insisted on longer heating, and in his vessels no micro-organisms developed. In this context, Pasteur showed that heated organic matter remained sterile unless contaminated but that, if contaminated, the previously heated material sustained life. This supported the conclusion that new life-forms only emerge from existing ones and provided additional evidence for the vitalist claim that living organisms are inherently different from non-living entities.

3 Developmental biology

Perhaps the greatest challenge for a mechanist, and the context in which vitalism retained its influence most strongly, was development. Beginning with an undifferentiated and singular egg, development results in an organism with a regular and differentiated structure. The problem is to explain how this regular differentiation is possible. Descartes defended an epigenetic view of embryological development; however, Descartes could not explain how a complex living organism could result from matter and motion (see Descartes, R. §8). This led Nicolas Malebranche (1638-1715) to develop a theory of preformation by *emboitement*, according to which the

germ cells contain, fully formed, the organism. During the seventeenth century, preformation offered a way of accommodating the view that mechanistic laws were insufficient as explanations of the construction of living organisms from unorganized matter. Pre-existence of the organism also avoided the atheistic and materialistic implications of a mechanistic epigenesis, by allowing that all organisms were preformed by the creator. Preformation was widely embraced by the beginning of the eighteenth century. Pierre-Louis Maupertuis (1698-1759), the Comte de Buffon (1713-81) and Needham took up the defence of epigenesis in mid-century, challenging preformationism. All three expanded the range of mechanisms available to include attractive forces. Faced with the problem of explaining the emergence of organization, Maupertuis attributed intelligence and memory to the smallest living particles. On the basis of experiments performed with Needham, Buffon proposed that the development of organisms depended on ‘penetrating forces’ analogous to gravity and magnetic attraction. Needham concluded that there was a ‘vegetative force’ which was the source of all the activities of life. These are vitalistic proposals, which make sense only within a mechanistic programme.

Similar problems persisted throughout the eighteenth and nineteenth centuries. Though Berzelius was mechanistic when faced with physiology, the production of organic form seemed to defy chemical explanation. He thus suggested there was a vital force differing from inorganic elements and regulating development. Charles Bonnet (1720-93), on the other side, was an enthusiastic champion of preformationism. He discovered parthenogenesis in the aphid, concluding that the female germ cell contained wholly preformed individuals, though he allowed that it need not be in exactly the form in which it exists in the adult organism. Beyond this he saw no explanation, emphasizing that the current state of physical knowledge does not allow any mechanical explanation of the formation of an animal. Bonnet embraced no vital forces, and therefore needed some primal organization.

At the end of the nineteenth century, analogous controversies resurfaced, though transformed and subject to experimental investigation. In investigating development, Wilhelm Roux (1831-1924) initiated an experimental version of *Entwicklungsmechanik* in support of internal determinants of development. He embraced a ‘mosaic’ theory of development, according to which the hereditary determinants are distributed in a qualitatively uneven way within the fertilized egg. As the cell divides, the daughter cells are genetically differentiated and these differences explain the differentiation of organisms. In 1888, Roux described experiments designed to test the idea of embryonic self-differentiation. At the first cleavage in the development of a frog, he destroyed one blastomere with a hot needle. In about 20 per cent of the cases, the remaining blastomere continued to develop, and it developed into half an embryo. He concluded that blastomeres develop independently, depending primarily on their internal constitution. This supported the view that development was controlled by material that was successively divided among the cells of the organism. This material, he thought, determined the growth of the organism in a fully mechanical form. In 1891, Driesch performed what seemed at first to be a very similar experiment, but with dramatically different results. Using sea urchins, he separated the blastomeres at the two-cell stage. Each blastomere developed into a smaller but complete blastula. He saw this result as inconsistent with Roux’s mechanistic account and, in particular, as inconsistent with the idea that division of the cell involved a division of the ‘germ’ controlling development. Since the blastomeres have the ability to develop into complete organisms, there could not be the kind of internal differentiation and control Roux had observed. Driesch initially sought external epigenetic factors to explain development. He came to see development as the response of a living organism rather than a mechanically predetermined process. He did not deny that physical and chemical processes are manifested in development, but held that the timing of development requires some special explanation. Physical laws thus place constraints on possibilities, but leave the actual outcome underdetermined. The connections were not immediately made, but Driesch was eventually led to a teleological and vitalistic view of development which he thought could explain developmental patterns.

4 Conclusion

Vitalism now has no credibility. This is sometimes credited to the view that vitalism posits an unknowable factor in explaining life; and further, vitalism is often viewed as unfalsifiable, and therefore a pernicious metaphysical doctrine. Ernst Mayr, for example, says that vitalism ‘ virtually leaves the realm of science by falling back on an unknown and presumably unknowable factor’ (1982: 52). C.G. Hempel, by contrast, insists that the fault with vitalism is not that it posits entities which cannot be observed, but that such explanations ‘ render all statements about entelechies inaccessible to empirical test and thus devoid of empirical meaning’ because no methods of test, however indirect, are provided (1965: 257). The central problem is that vitalism offers no definite predictions.

Neither complaint has much historical credibility. Many vitalists were in fact accomplished experimentalists, including most notably Pasteur and Driesch. Moreover, vitalists took great pains to subject their views to experimental test. Magendie, for example, insisted on the importance of precise quantitative laws. Vitalism, as much as mechanistic alternatives, was often deeply embedded in an empirical and experimental programme. Typically, vitalists reacted to perceived inadequacies of mechanistic explanations; in many cases they rightly recognized that the forms of mechanism, materialism or reductionism advocated by their contemporaries were undercut on empirical grounds. In the end, though, their own proposals were supplemented by empirically more adequate mechanistic accounts.

Vitoria, Francisco de (*c.*1486-1546)

Francisco de Vitoria, who spent most of his working life as Prime Professor of Theology at Salamanca, Spain, was one of the most influential political theorists in sixteenth-century Catholic Europe. By profession he was a theologian, but like all theologians of the period he regarded theology as the 'mother of sciences', whose domain covered everything governed by divine or natural, rather than human, law; everything, that is, which belonged to what we would describe as jurisprudence. Vitoria's writings covered a wide variety of topics, from the possibility of magic to the acceptability of suicide. But it is on those which deal with the most contentious juridical issues of the period - the nature of civil power and of kingship, the power of the papacy and, above all, the legitimacy of the Spanish conquest of America - that his fame chiefly rests.

1 Rights and political authority

It was one of Vitoria's central concerns that all rights (*iura*) were natural and the consequence of God's law not of God's grace. The contrasting claim, made first by the fourteenth-century English theologian John Wyclif (§4), then by the fifteenth-century Bohemian reformer Jan Hus. More recently, and far more menacingly, what Vitoria referred to as 'the modern heretics', the Lutherans, made rights, and hence the authority of secular princes, dependent upon God's grace. On this account only a godly ruler could be a just legislator. Thus, if a prince was a heretic or proved, in the eyes of those who chose to judge him, to be in a state of sin, his laws could not be binding in conscience and he might legitimately be deposed. For Vitoria it was vital that such a theory, with all that it implied for the effective right of lesser magistrates to make war upon their ordained princes, should be discredited.

All civil power, for Vitoria, is vested in the commonwealth since, if all societies are natural organisms, it follows that no individual could have held power prior to their formation. It follows too that if, as he said in *De poteste civili (On Civil Power)* (1528), 'legislative power exists in the commonwealth by Divine and Natural Law', the commonwealth may, and indeed if it is to constitute a civil society where there can be only one ruler, *must*, 'delegate its power and offices'. The person or persons to whom it delegates may, of course, be one or many. In the traditional Aristotelian division, with which Vitoria was familiar, there were three types of political rule: monarchy, aristocracy and timocracy (or democracy). Of these Vitoria, like Aristotle, unsurprisingly, considers that 'the greatest and best of all forms of rule and magistracy is monarchy or kingship'. The power exercised by monarchy, apart from being the most common form of rule (or so the historical record would suggest), and hence the most natural, is also of a different order from all others. It is the power to act on behalf of the community - what we today would call the 'high executive prerogative' of the state - and for Vitoria it 'is not from the commonwealth, but from God himself'. Such power, however, is what he calls a 'capability'. It cannot be exercised by an individual monarch until he has received ‘authority or executive power’ from the community. For the king may be the ultimate source of law, but he is also subject to the laws he makes, and these must always be in accordance with the customs of the commonwealth for which they are intended. There is, however, some doubt as to whether he may be coerced in any way if he fails to behave like a subject. Vitoria was willing to admit the possibility of tyrannicide on the grounds that, as he said in *De iure (On Law)* (1533-4) 'even if the commonwealth has given away its authority, it nevertheless keeps its natural right to defend itself'. But, in common with all early-modern political theorists on both sides of the confessional divide, he was also reluctant to ascribe coercive, and thus potentially revolutionary powers, to any authority other than that of the established ruler, whatever his conduct might be.

This conception of power, inevitably, played a central role in Vitoria's observations on the most pressing, and certainly the most intractable, issue in contemporary political theory: the legitimation of the Spanish conquest of America.

2 The Spanish conquest of America

Vitoria composed two treatises on the subject of the Spanish conquest of America: *De Indis (On the American Indians)* (1539) and *De iure belli (On the Law of War)* (1539). Both are answers to the question: By what laws were the barbarians subjected to Spanish rule? The answer to this question, however, turned upon another: Had the Indians, in fact, enjoyed property rights (*dominium*) over their own affairs, and over the territories they occupied, before the arrival of the Spaniards?

There could be, Vitoria argued, only three possible grounds for the Castilian crown's claim that the Indians were not, as were all other men, the subject of natural rights: either that they were sinners, non-Christians, madmen (*insensati*) or simpletons (*amentes*). The first of these invoked, once again, the Lutheran supposition that rights depended not upon God's laws, but upon God's grace. Man, argued Vitoria, is a rational creature and cannot lose that characteristic through sin, any more than he can willingly renounce his natural rights. He therefore concluded 'that, although the Indians were undeniably barbarians, they undoubtedly possessed the same rights, both public and private as any Christians'. This made any a priori claim to rights of conquests, or the claim to have occupied previously unoccupied territory - the so-called 'right of discovery' - invalid.

Vitoria also rejected the widely discussed claim that the Indians might be 'slaves by nature' largely on the empirical grounds that the Indians clearly did have 'some kind of rational order in their affairs'. They lived in cities, had a recognized form of marriage, magistrates, rulers, laws, industry and commerce, 'all of which require the use of reason'.

None of these arguments could provide the Castilian crown with rights to either sovereignty or property in America. Vitoria believed, however, that the Spaniards might legitimately claim a right drawn from the 'law of nations' - the *ius gentium*. This he called 'the right of natural partnership and communication'. There was nothing new in this argument, but Vitoria's formulation of it has won him the reputation of being the 'father of international law'. The seas, shores and harbours are, he argued, necessary to man's survival as a civil being, and must, therefore, be common to all. There was also, under the legal definition given to 'communication', an implied right to trade. If it could be said that the Spaniards had originally come to America as ambassadors, travellers and traders, they had to be treated with respect and be permitted access to all those who wished to trade with them. Vitoria also argued that the laws of nations granted the Spaniards the right to preach their religion without interference (although it did not oblige the Indians to listen) and that it permitted them to wage a just war 'in defence of the innocent against tyranny'.

The Spaniards could enforce these rights if opposed because any attempt to deprive a man of his rights constitutes an injury, and the vindication of injuries provides grounds for a just war. By the terms of a just war the victor acquires the status of a judge and may, therefore, appropriate the property of the vanquished. Similarly prisoners taken in a just war may legitimately be enslaved (see War and peace, philosophy of §§3, 6).

The Castilian crown could claim that its conquests had been 'just wars' only if, in fact, the Indians had 'injured' the Spaniards by denying them access to their lands, or if they had attempted to prevent them from preaching. If, however, as seemed overwhelmingly the case, they had done none of these things, then all that Vitoria was left with was the claim that, since the Spaniards were there already, any attempt to abandon the new American colonies would only result in 'a huge loss to the royal exchequer, which would be intolerable'. However, he argued, there was no evidence that the Portuguese in Africa had gained less by licit trade than the Castilians had gained in America by illicit occupation.

Vitoria's writings on power and the rights of conquest effectively set the agenda for most subsequent discussions on those subjects in Catholic Europe until the late seventeenth century. In Spain his rulings - as they came to be seen - on the legitimation of the colonization of America became something of an orthodoxy. They also provided much of the theoretical underpinning for an extensive body of ethnographical writings on the American Indians. And although it is clearly false to speak of Vitoria as the father of anything so generalized, and modern, as 'International Law', it is the case that his writings became an integral part of later attempts to introduce some regulative principle into international relations (see International relations, philosophy of).

Vives, Juan Luis (1493-1540)

Vives, Spanish humanist and educational reformer, was an eclectic but independent thinker, blending Aristotelianism and Stoicism with Christianity. He wrote on philosophy and psychology, religion and social concerns, and a wide range of subjects related to education. He was known by his contemporaries both for his lively attack on scholastic logic and for his practical judgment, or common sense. Familiar with classical, Christian and contemporary literature, he believed, with the Stoics, that learning should be applied for the common good. His original contributions are associated with an empirical approach to the sciences and the observation of nature, and his interest in the practical arts and inventions.

His social concerns included international politics (in which he is always a pacifist), and the relief of the poor in cities. His most scholarly work was an edition, with commentaries, of Augustine's De civitate Dei (The City of God) (1522), but he is best known for his pioneer work on psychology and educational reform. De anima et vita (On the Soul and Life) (1538) offers the first empirical study of the emotions and their relations with the body, based on Galen's theory of humours, and enriched with insights from Vives' lifelong observation of human nature and conduct. De disciplinis (On Instruction) (1531), the outstanding work on education in the sixteenth century, is nothing less than a programme for education from infancy to old age, with due emphasis on moral training and, in the case of the study of nature, reverence for its creator.

1 Life and works

Vives was born in Valencia to Jewish parents who had converted to Christianity. At sixteen he was sent to the University of Paris, and spent the rest of his life in exile. His parents were burnt by the Inquisition as relapsed Jews; he kept their fate to himself. His identification with his native country remained strong, and he proudly used the cognomen Valentinus, but he never saw Spain again. He taught at Louvain and Oxford and associated with the great Northern humanists, especially with his friends Erasmus, More and the French humanist Guillaume Budé. While at Oxford he attended the court of Henry VIII and Catherine of Aragon and was tutor to their daughter, Mary. He was expelled from England for taking Catherine's side in the divorce, and returned to Bruges where he died twelve years later.

At the College of Montaigu in Paris, Vives was drilled for three years in terminist logic and medieval physics. His exasperation at the abstract, sterile speculations, barbarous Latin and combative disputations of the scholastics prompted the book he published in Louvain in 1519, *Adversus pseudodialecticos (Against the False Dialecticians)*, which established him as a prominent figure in the conflict with the scholastic dialecticians (see Logic, Renaissance §2). When he left Paris in 1512 Vives settled among the Spanish colony in Bruges. Here, except for periods in Louvain and England, he was to spend the rest of his life, and here he married, in 1524, Margaret Valdaura of an old Valencian family.

From 1517 to 1523 Vives was at Louvain, teaching privately and at the university. At Erasmus' urging in 1520 he undertook his edition, with expansive commentaries, of Augustine's *De civitate Dei (The City of God)*, which he completed in 1522 and dedicated to Henry VIII. (This is the only major work of Vives not included in the *Opera Omnia* (1555) because it was frowned upon by the church for its dedication and its warm praise of Erasmus, as well as for the heterodoxy of some of Vives' notes; it ended up on the *Index Expurgatorius*.) In 1523, at Cardinal Wolsey's invitation, he went to teach at Oxford. In preparation for his visit to England, he composed and dedicated to his compatriot, Queen Catherine of Aragon, his treatise *Index Expurgatorius (On the Education of a Christian Woman)* (1524). Vives' Spanish austerity towards women gives the book a medieval flavour - for example: 'A woman's greatest ornament is silence' (*De Institutione*: 1 xi.136). More generous is the popular little handbook of morals and manners, blending stoicism and Christianity, which he prepared for the Princess Mary and called *Introductio ad Sapientiam (Introduction to Wisdom)* (1530).

Vives spent the better part of five years in England. He was professor of Latin, Greek and rhetoric at Corpus Christi College, and left his mark on Oxford through humanistic changes and improvements in the curriculum. He complained about the climate, but enjoyed the company of the great English humanists, More, Linacre and Fisher, and began to address himself to problems of a social and political nature. It was during this period that he wrote the original and important work on poor relief which he dedicated to the city of Bruges, *De subventione Pauperum*

(On Assistance to the Poor).

Vives' loyalty to Henry's Spanish queen in the matter of the divorce ended his association with the English court, and he went home to Bruges to devote the rest of his life to writing. During those dozen years of poverty and failing health, racked with gout, he produced his major works. These included *De disciplinis (On Instruction)* (1531) and *De anima et vita* (1538). The eight books *De artibu (On the Arts)*, which were published as Part III of *De disciplinis*, consisted of five books on logic (including 'De censura veri' and 'De instrumento probabilitatis') and three ('De prima philosophia') on Aristotelian physics and metaphysics from a Christian viewpoint. In this period he also produced the most popular of his books on education, *Linguae Latinae Exercitio (Use of the Latin Language)* (1539), which, in twenty-five entertaining dialogues, employs all the Latin words in current usage. A posthumous work, *De veritate fidei Christianae (On the Verity of the Christian Faith)*, intended for the conversion of pagans, Moors, Jews and heretics, was published in Basle in 1543.

2 Moral and political thought

Vives was a moral philosopher of sound and perceptive judgment, admirable for his sincerity and generosity of spirit. Erasmus said of him that he had a 'wonderfully philosophic mind' (*animo mire philosophico*). He was committed to the project of harmonizing Aristotelianism with Christianity and was sympathetic to the Stoic emphasis on personal virtue, inward tranquillity and social engagement. The writers he most often cites are Cicero, Seneca, Pliny, Plutarch and Quintilian. He once said there is no better Christian than a Stoic sage, and his own maxim was 'Without complaint' (*Sine querela*).

Accordingly, he was an *homme engagé*. He agreed with the Stoics that 'having acquired our knowledge we must turn it to usefulness and employ it for the common good' (*Opera Omnia*: vol. 6, 1.423). Deeply troubled by the political turmoil in Europe, he wrote urgently to heads of state and church on behalf of international peace among Christian nations; in *De Europae dissidiis et bello Turcico (On European Discord and the War with the Turks)* (1526), Vives urged that if they must employ their armies, they should unite against the encroaching Turks. His social concern found expression in his enlightened plan for poor relief, which was adopted by numerous Flemish cities. He also wrote a tract against the Anabaptists called *De communione rerum (On the Common Ownership of Goods)* (1535).

He was a staunch Christian. Like Erasmus, he said that if he differed from the church he would submit to it, but his personal religion tended more to ethical and spiritual values than to rite and observance, and it is significant that his ideal institutions, whether for poor relief or education, were intended to be secular. None the less his belief in God and the moral order of the universe was the foundation for all his thought, and piety was the motive and inspiration for his work.

3 Metaphysics and epistemology

Religion apart, his idea of the world and the place of people within it is essentially Aristotelian. Vives was known in his lifetime and after as a critic of Aristotle because of his incisive critique of Aristotle in *De disciplinis*. In fact he had read Aristotle more deeply than most other humanists, and had found him superior to all other philosophers. Vives identifies Aristotle's faults, but the Aristotelian systematization of knowledge based on self-evident first principles forms the basis of Vives' thinking about nature, matter and the mind.

In his metaphysics ('De prima philosophia') he discusses the creation of the world and the innate tendency of all peoples to believe in God. We are sorely hampered because of the Fall, but God has left us one priceless resource - a lively intelligence which is spontaneously active. Vives sometimes identifies this with 'natural light' (*lumen naturalis*), defined as those natural gifts given to us to enable us, through reason, to behold the truth. He accepts the Stoic doctrine of anticipations and common notions in the mind before birth (such as the innate belief among all peoples of the existence of God). From these first truths we gradually infer other truths, as plants grow from seeds. The order of knowledge is: sense perception, imagination, reason (composed of intelligence, memory and will) and judgment. To Vives a trained and enlightened judgment, based on experience, was the single most important quality for learning and life. He called it *prudentia*, that is, practical judgment or common sense. This is the surest guide to conduct. It is also the quality for which Vives was known by his contemporaries.

Vives is well aware of the limits to human reason. Of the three paths we have to knowledge: the senses, faith in

authority and reason based on the senses, none is infallible. Only God has perfect knowledge. Therefore Vives issues a strong caution at the beginning of the metaphysics, that we should not inquire into the intimate workings of nature. God has his own reasons for his creation and it is impious for man to seek, for example, to know about the elements, the forms of living things, and the number, magnitude, dispositions and powers of these things. Here Vives seems to be recalling with distaste the speculative natural philosophy characteristic of late scholasticism.

He is sceptical about the possibility of acquiring certain rational knowledge not only in theology but also about ordinary nature. Even here, he warns us, what knowledge we have gained can only be reckoned as probable, not as absolutely true. His scepticism did not, of course, extend to religious authority. Fundamental doctrines like the Fall were unquestioned, and in fact formed the basis for his doubts about certainty in human knowledge. In contrast with this is the optimism and confidence Vives expresses elsewhere over the progress of science and the open-endedness of learning. He declares that:

> Nature is not yet so effete and exhausted that she can bring forth, in our times, nothing comparable to those of earlier ages. She always remains equal to herself, and not rarely she comes forward stronger and more powerful than in the past…. Much is left for future generations to discover.
>
> (Preface to *De disciplinis*)

Perfect truth may be unattainable, but steady progress in knowledge can be made. By way of proof, Vives likes to point to the recent remarkable discoveries of ‘our [Spanish] countrymen’ beyond the ancient borders of the East and West.

4 Psychology and pedagogy

The new ingredient Vives brought to humanism was an empirical approach to the sciences. Having fled the closed scholastic world and embraced humanism and the classics, he moved a step further into the practical sphere. His original contribution lay in the importance he gave to observation and experiment in psychology, the teaching of natural history, law and medicine, and in his attitude towards the practical arts and inventions. He advocated the use of the vernacular in teaching young pupils, and in the presentation of laws, so that they could be understood by the people. His pragmatic voice is not that of the literary Erasmian humanist, but rather of the Spanish émigré in Bruges, heir to a long Jewish tradition of practical service in law and medicine, friend of merchants (he once held an export licence for his relatives), and especially of doctors and lawyers.

The last precept in Vives’ handbook of morals, The *Introduction to Wisdom*, is first to know oneself, and ultimately to know God. This rule he set out to implement in his two most important works, and to this task he brought his deep learning, critical spirit, and years of experience, observation and reflection on psychology and education.

The first of the two (though published second) was *De anima et vita* (1538), a pioneer work in psychology. Some consider it Vives’ masterpiece. It is an empirical study of the soul or mind and its interaction with the body. He classifies our emotions in relation to the Galenic humours (the four humours: blood, phlegm, yellow bile and black bile, which come to constitute the four classic temperaments: sanguine, phlegmatic, choleric and melancholic), describes how they are affected by internal and external circumstances (such as age, health, climate and events), and how they can be motivated and controlled by thought, judgment and will. Elsewhere Vives mentions the importance of this knowledge in politics and law, and it provides a foundation for his pedagogy (which is based on attention to individual capacities and their development).

The second, *De disciplinis* (1531), is a monumental work, divided into two parts, one critical, *De causis corruptarum artium (The Causes of the Corruption of the Arts)* and one constructive, *De tradendis disciplinis (The Transmission of the Arts)*. *De causis* traces the arts, or disciplines, from their beginning in our primitive human needs, through their growth by an empirical process, to their peak and decline. Decline was brought about sometimes by external causes (such as the barbarian invasions and the destruction by Goths and Vandals which produced the Dark Ages), most often by the weakness and vices of men and the emotions that cloud our reason. For example pride, arrogance and greed have diverted the pure study of astronomy into astrology, which is firmly to be shunned. *De tradendis* is a comprehensive programme for education from infancy to old age. No detail is overlooked, from physical requirements - site of the school, exercise, diet - to the bedside manner of the physician.

Much space is given to nature study, observation and experiment, backed for every subject by a selective and critical reading list ranging from the classics to contemporary sources. Higher studies follow, and professional training. Like Hippocrates, Vives links medicine with dietetics, and includes the composition of medicines, anatomy and dissection. He balances this with moral philosophy (ethics, politics, jurisprudence) and stresses the importance of historical studies. Nor does education stop there. After formal study one will turn one's interest to the arts and inventions that contribute to our daily life: food and shelter, gardening, architecture, travel, navigation. Finally, for the elderly, observing nature offers pleasant recreation, a walking exercise and sauce for the appetite.

Vives' originality as well as his sound judgment attracted many readers. Estelrich mentions nearly 500 editions of his works, 200 for the dialogues alone. In England his influence is evident in Elyot, Ascham and Milton, and he was read and quoted by the dramatist Ben Jonson. Some of his prayers found their way into the Book of Common Prayer. On the Continent his educational theories left their mark on Rabelais, Sturm and Comenius. As a critic of Aristotle he was read by Ramus and Gassendi, who also cited him for his emphasis on experiment. His scepticism about the reliability of knowledge, combined with an optimistic belief in the progress of science, appealed to Francisco Sanches and Montaigne (who also cited his edition of Augustine), as well as Gassendi. His theory of the emotions influenced Descartes' *Les passions de l'âme (The Passions of the Soul)* (1649). Finally, leaders of the Scottish school of Common Sense, Thomas Reid and Dugald Stewart, praised his theory of innate common notions, his emphasis on practical judgment, and his foresight as to the future of science. After a period of neglect he was rediscovered and read by such nineteenth- and twentieth-century scholars as Lange, Renan, Duhem, Dilthey and Cassirer.

List of works

Early writings and opuscula of Vives are currently being edited and translated by a group of scholars, notably J. Ijsewijn, C. Matheeusen, C. Fantazzi and E. George, and published by Leiden: Brill (1987-).

Vives, J.L. (1493-1540) *Opera Omnia (Complete Works)*, ed. G. Mayans y Siscar, Valencia, 1782-90, 8 vols; facsimile edn, London: Gregg Press, 1964.(Vives' complete works; following the *Opera Omnia* of 1555, this collection does not include Vives' commentary on Augustine's *De civitate Dei*.)

Vives, J.L. (1493-1540) *Obras Completas (Complete Works)*, ed. L. Riber, Madrid: Aguilar, 1947-8, 2 vols. (Spanish edition of Vives' works.)

Vives, J.L. (1519) *Adversus pseudodialecticos (Against the False Dialecticians)*, Louvain; trans. and ed. R. Guerlac, Synthese Historical Library 18, Dordrecht and Boston, MA: Reidel, 1979; C. Fantazzi (trans. and ed.) *In pseudodialecticos*, Leiden: Brill, 1979.(Critical editions of Vives' attack on scholastic dialecticians. The Guerlac edition also includes Books III and V-VII of *De causis*.)

Vives, J.L. (1522-8) *Literae virorum eruditorum ad Franciscum Craneveldium (Letters of Learned Men to Francis Craneveldt)*, ed. J. de Vocht, Louvain: Libraire universitaire, Uystpruyst, 1928.(An important biographical source, it includes letters between Vives and his friend Craneveldt.)

Vives, J.L. (1524) *De Institutione Feminae Christianae (On the Education of a Christian Woman)*, Antwerp: Hillenius; in G. Mayans y Siscar (ed.) *Opera Omnia*, London: Gregg Press, 1964, vol. 4, 65-301.

Vives, J.L. (1526) *De subventione Pauperum*, Bruges: Hubert de Crouck; in G. Mayans y Siscar (ed.) *Opera Omnia*, London: Gregg Press, 1964, vol. 4, 421-94; trans. A. Tobriner, *A Sixteenth Century Urban Report. Translation of Vives' On Assistance to the Poor*, Chicago, IL: University of Chicago Press, 1971.(One of Vives' important works of practical social philosophy; written during his stay in England.)

Vives, J.L. (1526) *De Europae dissidiis et bello Turcico (On European Discord and the War with the Turks)*, in G. Mayans y Siscar (ed.) *Opera Omnia*, vol. 6, London: Gregg Press, 1964.(Vives' attempt to reconcile European leaders.)

Vives, J.L. (1530) *Introductio ad Sapientiam*, Antwerp: Apud Martinum Caesarem; in G. Mayans y Siscar (ed.) *Opera Omnia*, London: Gregg Press, 1964, vol. 1, 1-48; trans. A. Tobriner, *Vives' Introduction to Wisdom, A Renaissance Textbook*, Chicago, IL: University of Chicago Press, 1968.(The little handbook of manners and morals written for Mary Tudor, daughter of Catherine of Aragon and Henry VIII.)

Vives, J.L. (1531) *De disciplinis (On Instruction)*, in G. Mayans y Siscar (ed.) *Opera Omnia*, London: Gregg Press, 1964, vol. 3, 82-297; vol. 6, 1-437.(Both parts of *De disciplinis* appear in the Gregg Press facsimile edition of Vives' works. The first part of this work, *De causis corruptarum artium*, has been translated into German by Sendnes and Hidalgo Serna, and English by Guerlac; the second part, *De tradendis disciplinis*, by

Watson. The third part, *De artibus*, was published posthumously in 1555.)

Vives, J.L. (1531) *De causis corruptarum artium (On the Causes of the Corruption of the Arts)*, in G. Mayans y Siscar (ed.) *Opera Omnia*, vol. 6, London: Gregg Press, 1964; German trans. W. Sendnes and E. Hidalgo Serna, Munich: Fink, 1990; English trans. R. Guerlac *De causis*, in preparation.(The first part of Vives' *De disciplinis*; traces the history of the arts, or disciplines.)

Vives, J.L. (1531) *De tradendis disciplinis (On the Transmission of the Arts)*, in G. Mayans y Siscar (ed.) *Opera Omnia*, vol. 6, London: Gregg Press, 1964; trans. F. Watson, *On Education, a translation of the 'De Tradendis Disciplinis'*, Cambridge: Cambridge University Press, 1913.(One of Vives' most important works on education; the second part of Vives' *De disciplinis*. The Watson translation provides a useful introduction to Vives's work.)

Vives, J.L. (1531) *De artibus (On the Arts)*, Antwerp: Apud Michaelem Hillenium, 1555; in G. Mayans y Siscar (ed.) *Opera Omnia*, London: Gregg Press, 1964, vol. 3, 82-297.(Published after Vives' death as the third part of *De disciplinis*; includes five books on logic and three on Aristotelian physics and metaphysics, all from a Christian viewpoint.)

Vives, J.L. (1535) *De communione rerum (On the Common Ownership of Goods)*, in G. Mayans y Siscar (ed.) *Opera Omnia*, vol. 5, London: Gregg Press, 1964.(A tract written to oppose the Anabaptists.)

Vives, J.L. (1538) *De anima et vita (On the Soul and Life)*, trans. into Italian and ed. M. Sancipriano, Padua: Gregoriana, 1974.(Critical edition of Vives' groundbreaking work on psychology.)

Vives, J.L. (1539) *Linguae Latinae Exercitio (Use of the Latin Language)*, in G. Mayans y Siscar (ed.) *Opera Omnia*, London: Gregg Press, 1964, vol. 1, 283-408; trans. F. Watson, *Tudor School-boy Life, the Dialogues of Juan Luis Vives*, London: Dent, 1908; repr. London: Frank Cass, 1970.(Twenty-five entertaining dialogues, demonstrating all the Latin words in current usage; most popular of Vives' books on education.)

Vives, J.L. (1543) *De veritate fidei Christianae (On the Verity of the Christian Faith)*, Basle: Oporinus; in G. Mayans y Siscar (ed.) *Opera Omnia*, vol. 8, London: Gregg Press, 1964.(Intended for the conversion of pagans, Moors, Jews and heretics; published posthumously.)

Vlastos, Gregory (1907-91)

A leading figure in the study of ancient Greek philosophy, Vlastos was a pioneer in the application to ancient philosophers of the techniques of analytic philosophy. Concentrating on figures of early Greek philosophy, he made major contributions to the understanding of the Presocratics, Socrates and Plato. He saw the Presocratics as applying ethical concepts to nature which ultimately rendered nature intelligible. He distinguished between the early dialogues of Plato, which represent the philosophy of Plato's master Socrates - a philosophy the early Plato shared - and the middle dialogues in which Plato develops a transcendental metaphysics and rationalist epistemology to ground Socratic ethical concepts. Vlastos's work played a major role in bringing the history of philosophy into the mainstream of philosophical research.

1 Presocratic studies

Born in 1907 in Istanbul to a Greek father and a Scottish mother, Vlastos was brought up as a Protestant and moved to America to study for the ministry at the University of Chicago. An interest in philosophy took him to Harvard, where he completed a Ph.D. under Alfred North Whitehead in 1931. Accepting a teaching position at Queen's University in Ontario, he became heavily involved in causes of economic and social reform. He published articles in Christian journals and wrote several lively and insightful defences of Whiteheadian metaphysics.

In 1938, in what was to be the turning point in his career, he went to Cambridge to study ancient philosophy with F.M. Cornford. His research culminated in a paper, 'The Disorderly Motion in the Timaeus' (1939), which challenged the then almost unanimous view of Plato scholars, including Cornford, that the creation of the world described in the *Timaeus* was meant figuratively rather than literally. His work began a reassessment of the *Timaeus* which has tended to vindicate his literalist reading. After serving as an officer in the Royal Canadian Air Force during the Second World War, Vlastos returned to academia, setting out on an ambitious programme of examining Greek political ideas he saw as providing the foundations of philosophical thought. In 'Equality and Justice in Early Greek Cosmologies' (1947) he explained how democratic ideals of equality before the law shaped conceptions of cosmic justice held by Presocratic philosophers. By ascribing such ideals to nature, early philosophers naturalized justice on the one hand and rendered nature intelligible on the other.

In 1948 Vlastos joined the faculty of Cornell University, where he was able to imbibe from Max Black, Norman Malcolm, and Arthur Murphy the latest techniques of analytic philosophy, which, imported from Britain and Austria, was now sweeping the USA. His 'Theology and Philosophy in Early Greek Thought' (1952), a broad survey of religion in early Greek philosophy, argues for a middle ground between the view that the Presocratics were naturalists without religion (argued by Burnet 1930) and the view that they devised theologies of their own (Jaeger 1947): rather, they assimilate divine attributes to nature, thus naturalizing religious values. On the basis of his research Vlastos was able to argue effectively against two views of Presocratic development (both propounded, at different times, by Cornford (1912; 1952)), first that philosophy developed as a scientific reaction to a religious background, and second that it never provided a scientific alternative to religion, as Hippocratic medicine did. Vlastos argued that Presocratic thought was often scientific in spirit, but that it was most indebted to social-political ideas, such as those of justice and equality, that were projected onto nature. In other studies Vlastos examined the epistemology of Parmenides, defended a traditional reading of Heraclitus against a revisionist anti-flux reading by G.S. Kirk, reconstructed a consistent theory of matter for Anaxagoras and a naturalistic basis for ethics in Democritus. He convincingly refuted claims that Parmenides and Zeno of Elea were reacting to a Pythagorean theory of point-atoms - a widely held view originated by Paul Tannery (1930) and promulgated by Cornford (1939) and J.E. Raven (1948) - by showing that there was no evidence that the alleged theory ever existed (see Presocratic philosophy).

2 Platonic studies

Having returned to the sources of Greek philosophy, Vlastos was now ready to return to Plato. His essay 'The Third Man Argument in the *Parmenides*' (1954) was a watershed event in a number of ways. In the first place it marked not only Vlastos's re-entry into Plato studies, but his application of the tools of analytic philosophy to ancient philosophy. Second, its thesis that Plato's presentation of the argument provided a 'record of honest perplexity' satisfied no one and provoked immediate replies from leading philosophers on both sides of the

Atlantic, initially from Wilfrid Sellars and Peter Geach. But further, the ensuing controversy had the effect of bringing ancient philosophy into the mainstream of philosophical debate - whereas the history of philosophy was in danger of being marginalized by the ahistorical or anti-historical bias of analytic philosophy, particularly in the USA. Indeed, the paper came to serve as a kind of paradigm of a new style of analytic history of philosophy. In the controversy Vlastos more than held his own against clever readings of the Third Man Argument by insisting that any interpretation be grounded in the text. His hermeneutical principle was as follows: 'If history is an empirical discipline, so is the history of philosophy. And no one can practise the empirical method unless he is willing to submit even the most deeply entrenched presumptions - his own or those of others - to the arbitrament of factual data' (1973: 255).

In 1955 Vlastos accepted an appointment as Stuart Professor of Philosophy at Princeton University, where he founded a joint Ph.D. programme in classical philosophy in conjunction with the Classics Department, a programme which quickly became a model for the rigorous training of specialists in ancient philosophy. Students were attracted from around the world and graduates were sent out to the best universities to practise and teach the new methods. Vlastos also published important papers in ethics and social philosophy: 'Justice' (1957) and 'Justice and Equality' (1962), the latter of which was widely anthologized. In the 1960s he began a series of studies on Zeno of Elea which still provide the definitive exposition of that philosopher's thought. He also produced an important series of articles on Plato, many of which were collected in *Platonic Studies* (1973), ranging from discussions of slavery in Plato to technical analyses of predication. His studies combined close readings with broad-ranging scholarship and sophisticated philosophical analyses that often investigated Platonic theories in the light of modern philosophical interests. He did not, however, try to force Plato into a modern mould, but rather to indicate where he stood with respect to modern issues and how and why he differed. For instance, in studying Plato's characterization of degrees of reality, Vlastos argued that what is at stake is not degrees of existence, but degrees of cognitive reliability, linked with moral or aesthetic valuation. By attributing a higher degree of reality to Forms than sensible particulars, Plato was in part exploring the greater degree of cognitive reliability that universals have over particulars - though he should have settled for a theory positing kinds rather than degrees of reality.

One area in which his work was especially fruitful was the study of predication. His earlier paper on the Third Man Argument had laid out the premises of the argument and had focused attention on 'self-predication', that is, on claims of the form 'F-ness is F' (for example, 'Justice is just'), as the most vulnerable step of the argument, which was used against Plato to generate an infinite number of Forms, apparently using only Plato's own principles. In 1965 Vlastos realized that some of Plato's utterances of the form 'F-ness is G' could be taken as 'Pauline predications' (named by reference to St Paul's 'Charity is kind' and so on) and analysed as 'necessarily, whatever is F is G'. Subsequently he found Pauline predications in the *Protagoras* and the *Sophist*, but no evidence that Plato himself recognized the ambiguity in his own use of 'F-ness is G' expressions. In general, Vlastos held, Plato's own view of the Forms as paradigms kept him from seeing the dangers of self-predication.

3 Socratic studies

In 1975 Vlastos published *Plato's Universe*, a series of lectures which demonstrated how Plato's cosmology embodied scientific hypotheses despite its seemingly anti-scientific basis. The following year he retired from Princeton, becoming a permanent 'visiting' professor at the University of California, Berkeley, until his death in 1991, teaching classes, giving summer seminars on Socrates for postdoctoral students, and lecturing widely. He continued to publish on Plato, for instance, defending him against Karl Popper in 'The Theory of Social Justice in the *Polis* in Plato's *Republic*' (1977), where he argued that Plato does have a genuine normative and meta-normative theory of justice. But his work increasingly focused on Socrates. Vlastos had always seen Plato's philosophy as developing over time. Furthermore, he had long been convinced that the philosophy of Socrates could be reconstructed from Plato's early dialogues, which represent a fictionalized but historically faithful portrait of Plato's master. Now he tried to work out to his own satisfaction the details of a coherent philosophy for this enigmatic but, for Vlastos, highly sympathetic figure.

According to Vlastos, the Socrates of Plato's early dialogues is inconsistent in a number of important ways with the Socrates of the middle dialogues. We find that other sources, such as Aristotle and Xenophon, tend to attribute to Socrates the traits we find in the Socrates of the early dialogues, for example, that he is solely a moral

philosopher and claims to have no special knowlege. It is plausible to think that the early Plato agreed with his master and only abandoned the Socratic method as he became immersed in geometry as a result of his contact with the Pythagorean philosopher-mathematician-statesman Archytas on his first voyage to Sicily. Socrates' method is not one of mathematical demonstration, but of refutation, requiring that the interlocutor express his real opinions and have them examined; in pursuing this method Socrates can be ruthless, but he never misleads or cheats his opponent. His *elenchus* or method of refutation is not merely a negative method but yields positive results, for it is based on the (well-confirmed) hypothesis that everyone who holds a false belief holds a true belief which conflicts with it, whereas Socrates' set of beliefs is self-consistent, and hence true.

Socrates' disavowal of knowledge can be understood if we make a distinction between 'certain' (demonstrative) knowledge and 'elenctic' knowledge; the latter, being the fallible result of a dialectical process, does not measure up to the former. Since Socrates' method at best yields elenctic knowledge, he is justified in disavowing certain knowledge. Socrates holds that virtue is sufficient for happiness, though he does not make the stronger claim that virtue is identical to happiness: nonmoral goods can and do contribute to happiness, but only when used in conjunction with virtue.

Vlastos succeeded in reconstructing a philosopher's Socrates who is more theoretically interesting than any previous construct, and his teaching produced a new generation of students of Socrates who are continuing a lively debate. Vlastos's greatest talent was perhaps his ability to see in ancient texts arguments and concepts that had philosophical interest for modern thinkers. No other single individual has contributed more to making ancient philosophy a part of contemporary philosophical study in the Anglo-American tradition.

DANIEL W. GRAHAM

List of works

Vlastos, G. (1939) 'The Disorderly Motion in the *Timaeus*', *Classical Quarterly* 33: 71-83; also in Vlastos, 1995, vol. 2, 247-64.(An argument against the prevailing orthodoxy that read the creation story of the *Timaeus* allegorically, that it should be taken literally.)

Vlastos, G. (1947) 'Equality and Justice in Early Greek Cosmologies', *Classical Philology* 42: 156-78; also in Vlastos (1995), vol. 1, 57-88.(Shows the influence of Greek political ideas on the early Greek conception of the cosmos.)

Vlastos, G. (1952) 'Theology and Philosophy in Early Greek Thought', *Philosophical Quarterly* 2: 97-123; also in Vlastos (1995), vol. 1, 3-31.(Argues against Burnet (1930) that Presocratic thinkers were not mere naturalists and against Jaeger (1947) that they were not really theologians either; rather they attributed to nature divine properties.)

Vlastos, G. (1953) 'Review of J.E. Raven, Pythagoreans and Eleatics', *Gnomon* 25: 29-35; also in Vlastos (1995), vol.1, 80-88. (Convincingly criticizes the view shared by Tannery (1930), Cornford (1930), and Raven (1948) that Parmenides and the Eleatics were reacting to a Pythagorean theory of 'number atomism'. It now appears that there never was such a theory. Provides the basis for Vlastos' later studies of Zeno.)

Vlastos, G. (1954) 'The Third Man Argument in the *Parmenides*', *Philosophical Review* 63: 319-49; also in Vlastos (1995), vol. 2, 166-90.(By applying techniques of logical analysis to the Third Man Argument against Plato's Theory of Forms, the author raises discussion of the problem to a new level. His conclusion that the argument was a 'record of honest perplexity' on the part of Plato has been rejected by most scholars. But he challenges his critics to find textual evidence to show that Plato had a reply to the argument.)

Vlastos, G. (1955a) 'Review of F.M. Cornford, *Principium Sapientiae*', *Gnomon* 27: 65-76; also in Vlastos (1995), vol. 1, 112-23.(Uses a superior understanding of scientific method to criticize his mentor's interpretation (Cornford 1952) of the Greek medical writers as scientific, the Ionian Presocratics as unscientific. Also rejects Cornford's earlier theory (1912) that philosophy had grown out of religion, in favour of a view that political ideas were decisive for the development of philosophy.)

Vlastos, G. (1955b) 'On Heraclitus', *American Journal of Philology* 76: 337-68; also in Vlastos (1995), vol. 1, 127-50.(Defence of a traditional reading of Heraclitus as philosopher of flux against Kirk (1952), showing the influence of earlier Ionian thought on Heraclitus.)

Vlastos, G. (1957) 'Justice', *Revue internationale de philosophie* 11: 324-43.(A study in moral and social philosophy arguing that agreement, contribution and need constitute 'irreducible components of the concept of justice'.)

Vlastos, G. (1962) ‘Justice and Equality’, in R. Brandt (ed.) *Social Justice*, Englewood Cliffs, NJ: Prentice Hall, 31-72.(Develops an equalitarian theory of justice based on natural rights which can accommodate unequal distribution of some goods. Reprinted in several anthologies of essays in moral philosophy.)

Vlastos, G. (1973) *Platonic Studies*, Princeton, NJ: Princeton University Press.(Collects many of Vlastos’s essays on Plato.)

Vlastos, G. (1975) *Plato’s Universe*, Seattle, WA: University of Washington Press.(Lectures on Plato’s cosmology and scientific method, arguing that Plato’s appeal to the supernatural paradoxically produced valuable scientific theories.)

Vlastos, G. (1977) ‘The Theory of Social Justice in the *Polis* in Plato’s *Republic*’, in H. North (ed.) *Interpretations of Plato*, Leiden: E.J. Brill, 1-40; also in Vlastos (1995), vol. 2, 69-103.(Arguing against Karl Popper’s criticisms of Plato, this paper maintains that there is a legitimate normative and meta-normative theory of justice in the *Republic*, one based not on inequality but on impartiality.)

Vlastos, G. (1991) *Socrates: Ironist and Moral Philosopher*, Cambridge: Cambridge University Press.(Vlastos’s major study of Socrates.)

Vlastos, G. (1994) *Socratic Studies*, ed. M. Burnyeat, Cambridge: Cambridge Unversity Press.(Essays on Socrates.)

Vlastos, G. (1995) *Studies in Ancient Philosophy*, ed. D.W. Graham, Princeton: Princeton University Press, 2 vols. (Collects those of Vlastos’s major essays which do not appear in *Platonic Studies*, *Socrates: Ironist and Moral Philosopher* and *Socratic Studies*. Volume 1: studies in the Presocratics; volume 2: studies on Socrates, Plato and later figures. Contains a complete bibliography of Vlastos’s work.)

Voegelin, Eric (1901-85)

Throughout his career, Voegelin was concerned with modernity; unlike his contemporaries he sought the explanation of its character and deformities (especially totalitarianism) in the restoration of 'political science' as Plato and Aristotle understood it. He therefore explored order in the individual's soul, political society, history and the universe, and its source in God. He did so by studying the representation of order in philosophy (Eastern as well as Western) and in revelation and myth. Voegelin concluded that 'gnosticism', the misinterpretation of the insights of myth, philosophy and revelation as descriptions of some future perfected society, and the wilful denial of transcendence and human limitation, represented the essence of modernity.

1 Life and works

By profession and self-description, Eric Voegelin was a political scientist, but philosopher, political theorist, theologian, mystic and intellectual historian would be equally accurate and equally misleading titles. Expelled by the Nazis from a lectureship at Vienna University, where he had studied, taken his Ph.D. and worked as Hans Kelsen's assistant, Voegelin lectured in political science at Baton Rouge, Louisiana from 1942 until 1958. He then took up Max Weber's former chair at Munich University. In 1969 he returned to the USA as Distinguished Scholar in the Hoover Institute, Stanford, California, and remained there until his death. His intellectual power and astonishing scholarly range have been widely acknowledged. His main endeavour was to reconstitute the study of politics, a project publicly initiated in his *The New Science of Politics* (1952) and partly executed in his *Order and History* (1956-87), as well as many other books and articles.

2 Critique of contemporary social science and philosophy

Voegelin's permanent concern was with order and disorder in the soul and in society, and the nature of modernity. Originally prompted by the rise of the totalitarian movements, of which he had first-hand experience, this concern was widely shared by academics. However, Voegelin's public stance was confrontational, and his insistence that knowledge of Mesopotamian, Israelite, Greek, Roman and medieval history and philology, as well as of myth and non-Western cultures, was indispensable to the restoration of a genuine science of order won him few friends. His condemnation of positivism was comprehensive, but he regarded the 1960s and 1970s debate between positivists and their opponents as merely a theoretically more impoverished re-run of its early twentieth-century predecessor (see Positivism in the social sciences). He interpreted both modernity and totalitarianism as 'gnosticism' (see §4). He made sweeping claims about the 'essence' of modern '-isms', 'climates of opinion', doctrines and movements, and about the mediations between these and the thought of the 'representative' thinkers he identified as their progenitors. His philosophical vocabulary is often difficult (drawing on Greek philosophy), and although bilingual and eloquent, he sometimes relies on a background of untranslatable German terms, most notably when he identifies 'the tension (*Spannung*) to the Ground (*Grund*) of divine Being (*Sein*)' as both the source and the object of the philosopher's quest (1956: 2).

3 Reality and consciousness

The questions Voegelin addresses are familiar to phenomenology and existentialism (Alfred Schütz was his lifelong friend, and he was deeply sympathetic to *L'homme révolté* of Camus), and were formulated in explicit critical confrontation with Kant, Hegel, Comte, Marx, Nietzsche, Weber, Husserl and Heidegger. Of contemporary philosophies, he found something to praise in every contemporary philosophy except positivism and Marxism, which (in his view) yielded virtually nothing valuable enough to compensate for their persistent 'prohibition' of fundamental questions.

At the centre of Voegelin's thinking is the metaphysical question of Leibniz, Schelling and Heidegger: Why is there something? Why not nothing? Why are things as they are? The quest for the answer is 'philosophy', which is not epistemology but the love of knowledge. Knowledge can only be knowledge of truth and reality, and reality is not merely or mainly to be found in external objects, which non-philosophical experience, ordinary language and ideologies suppose to exhaust reality. Reality is experienced in consciousness, which in its exploring never encounters anything in the universe which is not of its own 'substance'. What is encountered at the limit is a transcendent order, or structure, of being which has its Beginning or ground (*archê*) and its End (*telos*) in the

Beyond, or divine. And individuals (there is no consciousness except the consciousness of individuals) apprehend reality in this ultimate sense, not as external observers, but as ‘participant observers’. This reality, the ‘utterly real’ (*realissimum*) of myths, philosophers and mystics, the order of the universe and the ‘divine ground of [all] being’ that generates and sustains it and towards which it tends, is sought and found, the finding being experienced as the divine revealing itself: *theophany*.

There are three kinds of theophany: the wisdom of myth; ‘philosophy’ (paradigmatically Plato’s); and the Revelation of the Old Testament and (paradigmatically) Christ in Paul and St John. These are equally valid explorations of the experience of reality, compact in the case of myth, differentiated in philosophy and revelation. Each such exploration is culturally specific and personal (although the experiences are available to all who do not deliberately close them off), and becomes luminous only through language symbols. Some of these explorations have been epochal, rendering previous symbolizations (for example, the intra-cosmic gods of myth) obsolete and breaking historical time into a ‘before’ and ‘after’ the irruption of the divine. But none can ever be final, or perfectly adequate, or make sense independently of the experience of reality from which it arises.

Voegelin’s exploration of the nature of consciousness becomes ever more complex, since he must transcend solipsism and relativism, but rejects the privileged vantage point of the transcendental ego postulated by Kant, Fichte and Hegel; for Voegelin there is no such vantage point. And neither mystery nor the tensions inherent in the human ‘In-between’ are to be abolished. Nor must the symbols whereby this experience of transcendence and order becomes luminous be broken away from their engendering experience. Conversely, philosophical exploration of reality can never be symbol-free; consciousness and symbols always emerge from reality simultaneously, and language and experience are inseparable. The history of consciousness thus becomes a tracking of the trail of symbols and doctrines to their source in experience.

4 Gnosticism and political order

The experience of reality has profound implications, not only for the order of the philosopher’s or prophet’s own soul, but also for their apperception of true order in society and meaning in history. Voegelin’s historical work always centred on the former. As to the latter, he focused on ‘derailments’ and perversions of insight into order by ‘gnosticism’ (the essence of modernity) from antiquity onwards, culminating in totalitarianism (see Totalitarianism). His two attempts at a historical account of order in society and history foundered. In the 1940s, he abandoned an already well-advanced history of political ideas, because ideas, doctrines and doctrinal disputes of any sort are merely a lifeless (or pernicious) residue, when sundered from the experience which they symbolically articulate, or pervert. In *Order and History* (1956-87), Voegelin intended to present symbolizations of experience and their representation in political order as a meaningful historical sequence. His fidelity to evidence, however, made this impossible, and he came to see the idea of a unilinear history of mankind as itself misguided. ‘Mankind’ is a symbol intelligible only in the context of a common relation to the divine; empirically, mankind is no more a historic unity than ‘cat-kind’. He excoriated all equations of the history of mankind with the history of Western high culture, or what he called Western ecumenical imperialism. Nor, although there is meaning *in* history, is there a meaning *of* history. And any idea of a unilinear history terminating in the self-revelation (*egophany*) of a Condorcet, Hegel, Comte, Marx, Husserl or Heidegger, he saw as the height of the lust for power and a disease of the soul (see Historicism).

He construed such derailments as grounded in a refusal to recognize the inevitably circumscribed and uncertain character of human existence as the divine-human ‘In-between’ (Plato’s *metaxy*); this refusal makes man instead of God the measure of all things. Philosophers and prophets can counteract this evil only to a limited extent. The ground has already been occupied by others (individuals and societies) who claim to know reality and to be able accurately to represent it by the time that they arrive. The philosophers and prophets in turn can offer only symbolizations which are inevitably couched in an object-oriented language and are thus always liable to misrepresentation, especially since philosophy and myth have no certainties or definitive answers of their own to propound; and they cannot abolish empirical reality and its disorder and injustice. In particular they cannot abolish the profound sense of injustice of the subjects of ‘ethnic’ orders (that is, culturally cohesive and territorially limited polities) conquered by ‘ecumenical’ orders (polities aiming at a more or less inclusive empire). To such individuals, ‘ethnic’ orders had represented the order of the universe; ‘ecumenical’ empires represent nothing except the triumph of naked power.

Gnosticism, whether as a pernicious potential within Christianity, or stemming from other sources, insulates itself against reality by prohibiting metaphysical questions (notably Marx's ruling out such questions as irrelevant for 'socialist man'), and by 'immanentizing' (interpreting the symbols of transcendence as descriptions of some present or future perfect mankind or society). It may remain mere speculation, or it may become a political force in times of disorientation and disorder, taking the form of political activism, 'liberation', revolution or nihilism. Voegelin sees a similar, but less resolute and destructive infidelity to reality in doctrinaire religion and progressivism of all kinds.

It would have been absurd for Voegelin to present his own insights as a doctrine, even for the sake of remaking the now vanished link between symbols and their engendering experience provided in the past by myth, religion and authority. And it may be the case that humankind finds reality or uncertainty difficult to bear, especially when it lacks a stable institutional tradition and common sense (which the UK and the USA in Voegelin's view still had). Although he was no cultural pessimist, it did not surprise Voegelin that he did not 'find many, or favourable hearers'.

List of works

Voegelin, E. (1990-), *The Collected Works of Eric Voegelin*, series ed. P. Caringella, Baton Rouge, LA: Louisiana State University Press.(An exemplary edition which aims to present all of Voegelin's unpublished, as well as published, writings in thirty-four volumes. Volume 12, *Published Essays 1966-1985*, includes striking critiques of Hegel (as a 'magician') and Heidegger, literary interpretations and late statements of his theology and Christianity.)

Voegelin, E. (1952) *The New Science of Politics*, Chicago, IL, and London: University of Chicago Press.(The most widely known of Voegelin's writings, now superseded by later work but still a useful introduction to Voegelin's themes of representation, modernity and gnosticism. Often reprinted.)

Voegelin, E. (1959) *Wissenschaft, Politik und Gnosis*, Munich: Kösel; trans. W.J. Fitzpatrick, *Science, Politics and Gnosticism*, Chicago, IL: Regnery, 1968.(His most accessible, although polemical presentation in two essays, the former outlining the projected *Order and History*, the latter containing the most succinct exploration of *Gnosis* and the notorious critique of Marx; the translation includes an additional essay on 'Ersatz Religion'.)

Voegelin, E. (1956-87) *Order and History*, vol. I: *Israel and Revelation* (1956), vol. II: *The World of the Polis* (1957), vol. III: *Plato and Aristotle* (1957), vol. IV: *The Ecumenic Age* (1974), vol. V: *In Search of Order* (1987), Baton Rouge, LA: Louisiana State University Press.(The finest of Voegelin's productions. Posthumous and unfinished, it does not cover the Middle Ages, Reformation or Modernity; of especial note are the preface and 'Historiogenesis' in vol. IV.)

Voegelin, E. (1966) *Anamnesis*, Munich: R. Piper; abridged edn, trans. and ed. G. Niemeyer, Notre Dame, IN, and London: University of Notre Dame Press, 1978.(Good translation but omits some important early writings on Husserl; includes the fullest statements of Voegelin's philosophy of consciousness.)

Voegelin, E. (1975) *From Enlightenment to Revolution*, trans. J.H. Hallowell, Durham, NC: Duke University Press.(The only part of Voegelin's projected history of political ideas to be published in his lifetime; a very good introduction to Voegelin's thought; incisive exegesis of Voltaire, Helvétius, Comte and Marx *inter alia*.)

Voegelin, E. (1989) *Autobiographical Reflections*, ed. E. Sandoz, Baton Rouge, LA: Louisiana State University Press.(Fascinating insights into Voegelin's life, times and intellect.)

Voltaire (François-Marie Arouet) (1694-1778)

Voltaire remains the most celebrated representative of the reformers and free-thinkers whose writings define the movement of ideas in eighteenth-century France known as the Enlightenment. He was not, however, a systematic philosopher with an original, coherently argued world-view, but a philosophe *who translated, interpreted and vulgarized the work of other philosophers. His own writings on philosophical matters were deeply influenced by English empiricism and deism. His thought is marked by a pragmatic rationalism that led him, even in his early years, to view the world of speculative theorizing with a scepticism that was often expressed most effectively in his short stories. As a young man, Voltaire was particularly interested in Locke and Newton, and it was largely through his publications in the 1730s and 1740s that knowledge of Lockean epistemology and Newtonian cosmology entered France and eventually ensured the eclipse of Cartesianism.*

After his stay in England Voltaire became interested in philosophical optimism, and his thinking reflected closely Newton's view of a divinely ordered human condition, to which Alexander Pope gave powerful poetic expression in the Essay on Man (1733-4). This was reinforced for the young Voltaire by Leibnizian optimism, which offered the view that the material world, being necessarily the perfect creation of an omnipotent and beneficent God, was the 'best of all possible worlds', that is to say the form of creation chosen by God as being that in which the optimum amount of good could be enjoyed at the cost of the least amount of evil.

Voltaire's later dissatisfaction with optimistic theory brought with it a similar loss of faith in the notion of a meaningful order of nature, and his earlier acceptance of the reality of human freedom of decision-taking and action was replaced after 1748 with a growing conviction that such freedom was illusory. The 1750s witness Voltaire's final abandonment of optimism and providentialism in favour of a more deterministically orientated position in which a much bleaker view of human life and destiny predominates. Pessimistic fatalism was a temporary phase in his thinking, however, and was replaced in turn by a melioristic view in which he asserted the possibilities of limited human action in the face of a hostile and godless condition.

1 Life

Voltaire (born François-Marie Arouet) was one of the most prolific and controversial writers of *ancien régime* France, and his works encapsulate the spirit and ideology of the French Enlightenment. His writings, which span a broad spectrum of genres, do not readily provide the reader with a single, coherent philosophical system or even a systematically argued world-view. In fact, Voltaire deeply mistrusted systems and system-builders, and he frequently satirized, particularly in his later years, the terminology and theories of metaphysicians such as Spinoza, Descartes, Leibniz and Wolff (see LEIBNIZ, G.W.). He wrote mostly, though not exclusively, as a *philosophe* rather than as a philosopher, that is to say, as a dissident polemicist concerned more with persuasive forms of discourse, and the effective advancement of a programme of moral and political reform, than with the pursuit of abstract speculation and analysis *per se*. Some aspects of his philosophical thinking are conducted at an arguably superficial level in the form of short, satirical tales. The term 'philosopher', in its post-nineteenth-century sense, thus sits uneasily with Voltaire. Had he known about the modern meaning of the term, he would have dissociated himself from it. He remained deeply sceptical about the mission of philosophy, and the absurdity of metaphysics is a striking leitmotif of his writings.

In 1726, as the result of a scandal, Voltaire was exiled from Paris, and decided to go to London where he stayed until 1728. His stay in England enabled him to engage with the Baconian tradition of English empiricism and to familiarize himself with the work of Locke, Hobbes, Newton, Clarke, Berkeley, Collins and others. The impact of England on his thinking resulted in 1734 in the publication of the *Lettres philosophiques*, composed originally in English as the *Letters concerning the English Nation*. In 1734 he also started work on another important fruit of the English experience, the *Traité de métaphysique*. This is one of the few Voltairean treatises to contain sustained, relatively sophisticated, philosophical argument and analysis.

The controversy following the publication of the *Lettres philosophiques* forced Voltaire to flee Paris for the chateau of Mme Du Châtelet-Lomont at Cirey, where he stayed for the rest of the decade working on his most ambitious scientific achievement, the *Éléments de la philosophie de Newton* (1738). After a brief stay at Frederick the Great's court at Potsdam, Voltaire settled in Geneva in 1754-5, and the following decade saw the publication

of major historical, polemical and satirical works, including the anti-Leibnizian *Candide* (1759), the *Philosophie de l'histoire* (1759), the *Dictionnaire philosophique* (1764-9) and *Le Philosophe ignorant* (1766). The 1755 Lisbon earthquake proved to be a catalyst in his long debate with others and with himself on the problem of evil and predetermination, culminating in *Candide*, his most brilliant and enduring philosophical narrative.

Between his earliest writings on philosophical matters in 1734 and those works that appeared after 1755, his position changed from one of qualified deistic providentialism and belief in a logically ordered creation, whose harmony had been convincingly demonstrated by Newton's mathematical principles, to one of uncompromising rejection of providentialism and philosophical optimism. Voltaire has few claims to originality as an abstract thinker. As his commentaries in the *Lettres philosophiques* on the work of Francis Bacon, Locke and above all Newton show, he excels in the art of exposition and vulgarization. As a result, he occupies a uniquely influential position as a mediator and disseminator of English and German seventeenth-century philosophy in a France that was to remain dominated by Cartesianism until well into the 1740s. Newton and Locke, in particular, enter the French consciousness through Voltaire's pen.

2 Metaphysics and ethics: the *Traité de métaphysique*

Voltaire's early adherence to rational deism was reinforced in England, although the problems of theodicy and free will had started to preoccupy him well before his exile (see Deism). The first version of the *Traité de métaphysique* (1734) grew out of Voltaire's reactions to Locke's *Essay concerning Human Understanding* (1689), and its composition was shaped by the controversy aroused in France by the *Lettres philosophiques*. By 1736 the text had evolved to take in the implications of Alexander Pope's *Essay on Man* (1733-4), and included chapters dealing with ethics and with man as a social being, reflecting also the influence of Shaftesbury, Mandeville and Clarke. The philosophical balance of the *Traité* moved between 1734 and 1736 from metaphysics to ethics. The *Traité* consists of a brief introduction dealing with doubts about the nature of man, written in the sceptical tradition as transmitted to the eighteenth century through the writings of Montaigne and Le Mothe Le Vayer, followed by nine chapters. Voltaire's philosophy at this stage owes much to the theodicy of English deism and the optimism of Pope and Shaftesbury. The *Traité* also contains traces of the influence of ancient scepticism and epicureanism, the French Pyrrhonian tradition, and late seventeenth-century libertinism (see Libertins).

Much of the *Traité* is anchored to Lockean problems, the second, third, fifth, sixth, seventh and ninth chapters correlating closely to Locke's programme of epistemological investigation. Voltaire follows Locke in the rejection of innate ideas (attributed to Descartes), and in the location of the source of ideas in the senses and the reflective processes. He does not deal with reflection *per se* except to note that thought is not, *pace* Descartes, necessarily a spiritual attribute. Voltaire fully shared Locke's view of the limitations of human understanding, and epistemological modesty was to be the organizing theme of a later wide-ranging essay, *Le Philosophe ignorant*.

Voltaire's starting-point is an awareness of the relative combined with an insistence on the practical aspects of ethics and the lessons of natural morality. Establishing a significant order of priorities, his argument moves from man to God, bypassing Christian notions of creation and original sin. God's existence is deduced empirically in the second, and longest, chapter in the treatise, although knowledge of God's existence is not seen as being either universal or necessary to man's happiness. God's existence is argued from final causes and the Locke-Clarke propositions concerning necessity. The counter-arguments denying certainty in God's existence, and affirming the reality of evil as a negation of the possibility of belief in divine benevolence and omnipotence, are also expounded, but at this stage in Voltaire's thinking they are not allowed to undermine what was essentially a deistic position.

On the question of the soul, Voltaire's view in the *Traité* was that man was composed of thinking matter. He rejected the notion of thought itself as a material compound, but in 1734 he was not prepared to discount entirely the notion of the spirituality and immortality of the soul. He was to advance that argument even more positively in the article 'Ame' in the *Dictionnaire philosophique*. In spite of a tenacious belief in the existence of the soul, often identified with thought itself as a 'principle' invested in inert matter by God, Voltaire did not allow man to occupy a special, privileged place in nature. Man was just a 'reasonable animal'. Unlike the rest of creation, however, man had a measure of free will, although freedom and the power to act freely in accordance with the dictates of reason, always remained for Voltaire severely limited features of man's condition. But on freedom depended morality, and morality provided the focus for the last two chapters of the *Traité*.

Here Voltaire addressed the question of whether man was a social being, together with the related issue of vice and virtue. Concepts of good and evil were determined by what was useful or harmful to society. Parting company with Locke, Voltaire postulated, reflecting again a measure of inconsistency in his thinking, that man possessed innate moral sentiment and an instinct for justice. The assumption of universal morality followed logically from that, and supported the notion of legality, although Voltaire accepted at the same time that specific, contingent laws could well be diverse and contradictory in different parts of the world. Vice and virtue were seen to be relative to social contexts, as was man's understanding of what was useful. However, like Bayle, Voltaire accepted the proposition that all men concurred in the general notions of what was good or evil inherent in those natural laws on which all men in all societies ultimately agreed. Reflecting Shaftesbury's influence, Voltaire's view of human nature was determined by the premise that man possessed latent moral qualities derived from God, and he was never able to reconcile this successfully with his Lockean rejection of innate ideas in other contexts.

Much as God had given the bees a powerful instinct to organize the communal life of the hive, so he had given man, not moral instructions on how to behave, but certain instincts conducive to social and moral life. These were in addition to the instincts of sexuality and self-preservation common to all animals, and included benevolence, compassion, honour, love of truth, pride and the passions, of which even the unattractive, such as pride and envy, had teleological purpose, and served to promote the public good. In all this, God's role in human affairs remained remote and non-interventionist. Voltaire's moral philosophy was essentially a naturalist code in which his concern was less with logical argument than with a passionate determination to define man as an ethical being whose moral conduct and decisions owed nothing to theology or faith, but a great deal to the will to action.

3 Cosmology: *La Métaphysique de Newton*

When it first appeared in 1738, the *Éléments de la philosophie de Newton* was exclusively concerned with optics and gravitational theory, that is with 'natural philosophy', rather than with philosophy as such, and there is little reference to the 'Scholium generale' with which Newton had concluded his *Principia* (1687). However, the 1741 edition of the *Éléments* contained a nine-chapter essay prefacing the commentary on Newtonian physics. This had been printed separately in 1740 as *La Métaphysique de Newton, ou Parallèle des sentiments de Newton et de Leibniz*.

Much of this work is concerned with an exposition of the problems of free will, morality and the mind-body relationship, many of which had been raised earlier in the *Traité de métaphysique*. The new ground that Voltaire now broke concerned Leibniz, and the treatise represents Voltaire's most sustained analysis of Leibnizian science and cosmology. Voltaire's long engagement with Leibnizianism was to drive much of his thinking on questions relating to theodicy and philosophical optimism between 1740 and 1755, culminating in 1756 in his first major attack on optimistic theory in the *Poème sur le désastre de Lisbonne*, reinforced three years later in his satirical demolition of Leibnizian cosmology in *Candide*. Voltaire's attention had been drawn to Leibniz through the work of Christian von Wolff, who had systemized some of Leibniz's thoughts on logic and metaphysics, and whose merits had been commended to Voltaire by Mme Du Châtelet-Lomont and Frederick the Great. Voltaire's knowledge of Leibniz was also based on a Latin translation of the *Monadology* (1714), and he was familiar with the Leibniz-Clarke correspondence concerning space and time.

In *La Métaphysique de Newton* he resumed Newton's arguments from design as a proof of God's existence as a First Cause, outside time and space, of the contingent phenomena of the universe. Whereas in the *Traité de métaphysique* Voltaire's God had been an absent Prime Mover, in *La Métaphysique* he was more sympathetic to the providentialism that marked Newtonian assumptions of divine paternalism. Voltaire still managed to deflect the paradoxes presented by the spectacle of man's suffering and experience of evil, although in *La Métaphysique* the problem of theodicy was raised again in the context of man's freedom to act within the parameters inherent in a providentially ordered human condition. It was here that Leibniz entered the discussion with reference to sufficient reason, necessity and contingency, matters upon which Voltaire had already exchanged views with Clarke. Like Clarke, he argued that divine omnipotence would be compromised if God's will was made subject to the principle of sufficient reason. Voltaire preferred the Newtonian position in which God is seen to have made many things, the reason for whose existence is God's will alone.

Voltaire avoided determinism at this stage in his thought by preserving, by means of extended implication, the capacity for unmotivated choice arising from 'liberty of indifference'. His position on 'liberty of indifference' was

not consistent or rigorously applied, however, and elsewhere - in the *Discours en vers sur l'homme* (1738-42), for example - this received less emphasis than the Lockean view that man's freedom consisted in the power to act and put conscious choices into effect, the question of motivation or absence of motivation being irrelevant. On the question of freedom, and free will in general, Voltaire's views were to change radically, and by the 1750s his position was much more deterministic.

Despite his acceptance of Newtonian arguments from design as proof of an ordered universe in *La Métaphysique*, signs of contradiction and traces of scepticism, to be more strongly articulated at a later stage, were already surfacing in Voltaire's discussion of Leibniz's arguments relating to sufficient reason and to the existence of simple substances, or monads. Leibnizian monadology underpinned the elaboration of the Great Chain of Being theory and the postulation of a cosmos of active metaphysical atoms, or monads, each following a programme of dynamic evolution established by the Creator, and each in harmony with other monads, one of their more controversial characteristics being perceptivity. This infinite multitude of monads constituted a metaphysical substratum of the world of material reality and conscious experience. Voltaire measured Leibniz's theory of monads by simplistically empirical criteria that he associated with Lockean epistemology and Newtonian mathematics. His approach reflected only a partial understanding of the *Theodicy* (1710) and the *Monadology*, and incoporated a great deal of caricatural commentary.

Voltaire objected that Leibniz's postulation of a cosmos of infinitely divisible, nonmaterial and nonspatial matter as an integral component of the material cosmos was self-contradictory. Any explanation of matter that involved the nonmaterial was fanciful, and the notion of perceptivity in all monads, including those constituting inanimate matter, was against common sense. He countered with arguments not entirely free of speculation themselves, drawn from Newtonian science, and advanced a view of matter whose atomic structure was diverse but immutable. Change was accounted for in terms of the effects of gravitational attraction, the 'active force which sets everything in the universe in motion'. Newtonian physics and cosmology did solve for Voltaire some of the philosophical problems arising from his study of Leibnizian monadology and harmony. After 1741, however, notwithstanding his deep admiration for Newton's empirical rigour, he was to have little more to say about Newton. His preoccupation with Leibnizianism, and with its broader philosophical implications, would continue, on the other hand, for many decades.

4 Optimism and freedom

Voltaire's engagement with the problem of evil arose as part of a general broadening of his philosophical interests during his stay in England. Prior to that, he might have already gained some awareness of the issues through the well-publicized debate on theodicy that had taken place between 1697 and 1716 between Archbishop King, Bayle and Leibniz. It was, however, Pope's *Essay on Man* that fired his interest initially in the philosophical issues generated by optimistic theory.

The first serious discussion of the implications of optimism had occurred in the *Traité de métaphysique* where Voltaire had been concerned almost exclusively, as was Pope, with mounting an effective defence of deism against the objections of the atheists. The central argument in this defence related to the question of human ignorance. Voltaire sought to account for evil in terms of a contingent, rather than transcendental, phenomenon, whose nature and effects were falsely determined by the partial, imperfect nature of human understanding. Evil was relative, and to ascribe to God injustice and cruelty was as meaningless as to call him blue or square. The human mind could not conceive of perfection on a cosmic scale, and thus assertions of imperfection were necessarily flawed. Any moral judgment on God's creation must therefore be suspended for lack of evidence.

While Voltaire never quite shared Pope's confidence in providence as an unambiguously benevolent force in human affairs, his early views can be aligned with Pope's 'Whatever is, is right' formulation, and this was fully reflected in his own *Discours en vers sur l'homme* (see especially Part 6). However, the problem of theodicy had been deflected rather than resolved, and after 1740 it re-emerged in Voltaire's thought as a major issue. By 1740 he was aware of Leibniz's arguments on the *Theodicy* as these related to evil, not as a contingent but as an absolute, universal phenomenon that sought to leave intact the providentialist thesis of creation as the work of a beneficent and omnipotent God. Dogmatic promulgation of Leibnizian optimism by German commentators such as Wolff and Kahle became increasingly a subject for ridicule and caustic satire in Voltaire's letters and works. Leibnizian optimism, immortalized in the figure of Candide's tutor, Dr Pangloss, soon came to exemplify for him

the irrelevance of speculative metaphysics to the real world of human suffering and everyday experience.

The evolution of Voltaire's position with regard to Pope and Leibniz, and the related problems of evil, optimism and freedom, is best illustrated not in treatises but in Voltaire's short philosophical stories, and in particular in *Zadig, ou la destinée* (1748) and *Candide, ou l'optimisme*. In *Zadig* he approached the problem of evil from the standpoint of human destiny. Using dialogic format he distilled philosophical optimism into three main propositions that were not argued, or even endorsed, but asserted arbitrarily by an angelic *persona* as articles of faith: chance does not exist; man's destiny is organized in a beneficent way, immutably determined by providence; every apparent evil is part of a larger good and is impenetrable to limited human logic and understanding. While 'Whatever is, is right' still obtained in theory, by 1748 Voltaire no longer adhered fully to his earlier view that evil had no absolute reality. In *Zadig* the focus of attention is clearly on the realities of human suffering and the illogicality of the human predicament rather than on the metaphysical rationale for its existence. Man's place in the Great Chain of Being might have been alloted to him by God for an unknowable purpose, but Voltaire was now firmly of the view that while transcendental perspectives may help to explain the human condition, they contributed nothing to the alleviation of that condition, or to the resolution of the problems that it posed for individual freedom and action.

In the 1750s Voltaire's thinking was dominated by an awareness of the immediacy of evil in day-to-day human experience, and this gradually undermined his earlier sympathy for the optimistic-providentialist position. Events such as the 1755 Lisbon earthquake and the Seven Years War offered further brutal proof of the sterility of optimistic theory, and the darker tones of Voltaire's world-view emerged clearly in the *Poème sur le désastre de Lisbonne*. It was in this didactic poem that he first gave explicit expression to what had by now become his principal objection to the providentialist axiom that all was for the best in the best of all possible worlds. Such a philosophy was now nothing less than a doctrine of despair and a denial of human freedom and of human capacity for action. Philosophical optimism had nothing to offer the stricken citizens of Lisbon.

On the question of free will, Voltaire's earliest discussion of the problem is to be found in the seventh chapter of the *Traité de métaphysique*, where he had accepted that to will and to act accordingly was to be free. Freedom, however, was relative and, even at this 'optimistic' stage in his thinking, it was almost without constraints. He developed his thoughts on freedom further in 1737 in *De La Liberté*. Here he made use of the Lockean definition of freedom as being the choice of whether to act or to refrain from acting, but he now preferred to concentrate on 'power of self-motion' (Clarke's phrase) as being the only true source of freedom. By the mid-1750s Voltaire's views on freedom had evolved considerably, and in ways that mirrored his change of direction with regard to providentialism and philosophical optimism. His denial of free will, and his scepticism with regard to the notion of freedom in human decision-taking and action, was now complete, and it is set out in the fifty-six 'doubts' that constitute the *Doutes sur la liberté* (1752) (see also the articles 'Destin', 'Franc arbitre' and 'Liberté' in the *Dictionnaire philosophique*). Little trace remained of the arguments against determinism that had characterized the *Traité de métaphysique* and *De La Liberté* some two decades earlier, in which a high value had been placed on man's power of judgment and his power to act on that judgment. Men, like animals, are determined by 'instinct' and by 'ideas' that they receive but over whose reception they have no control, and man is subject to the same laws of necessity that govern the whole of nature. The deep sense of futility that was to permeate *Candide* permeates also his list of doubts (see particularly the fourteenth).

Voltaire's loss of faith in philosophical activity reached its climax in *Candide*, in which he finally turned his back on the 'métaphysico-théologo-cosmolonigologie' of Dr Pangloss. Candide inhabits a bleak, arbitrary and possibly godless universe in which evil is an omnipresent, crushing reality. Man might be the victim of forces beyond his control, but experience (not philosophy) taught Candide that the potential for limited, but effective, action still lay within man's grasp: 'Il faut cultiver le jardin' (We must cultivate the garden). The point of thought was action, not the construction of inconclusive speculative systems.

Voluntarism

Voluntarism is a theory of action. It traces our actions less to our intellects and natural inclinations than to simple will or free choice. Applied to thinking about God's actions, voluntarism led late medieval philosophers to see the world's causal and moral orders as finally rooted in God's sheer free choice, and to take God's commands as the source of moral obligation. Medieval voluntarism helped pave the way for empiricism, Cartesian doubt about the senses, legal positivism and Reformation theology.

Our wants and our natures (including our rationality) help shape our choices and actions. Intellectualists and voluntarists offer rival views of how great a role these factors play. Aquinas (§§12-13), a major intellectualist, held that our will is a rational appetite, a desire for items we think good for us. Its nature is to choose what we judge good for us; we can choose among actions because different acts can seem good to us in different respects. We can err about what is good for us, or fail to will it. But we cannot knowingly reject anything that seems to us the best in the circumstances. Further, while our wills do influence our intellects, we cannot determine our intellects to accept beliefs in the face of sufficient evidence against them. So Aquinas sees our passions (which shape what seems good to us), our nature as good-seekers and our intellects as moulding our choices.

Duns Scotus (§14) adds a second rational desire to Aquinas' picture. Anselm of Canterbury (§6) held that we have a will for what seems good for us and also a will for moral rectitude. Scotus generalizes Anselm's second 'will': for him, we naturally incline to what seems good for us, but also naturally love things for their objective goodness. So we can reject what seems best for us if we desire more what seems objectively best, or reject what seems objectively best if we desire more what seems best for us: our natures leave us a wider range of choice. Yet both natural will-inclinations are towards good. So we still cannot knowingly reject happiness or whatever else seems best in the circumstances both objectively and for us.

William of Ockham (§10) tends towards voluntarism. For Ockham, it is false that we can choose freely because we have intellects or rational desires: it is just a basic fact about us that we can do so. So our will is independent of reason and natural inclination. Neither restricts our choices. Ockham thinks we can knowingly reject happiness or whatever else seems in all ways best, and will evil because it is evil rather than because we think it in some way good. If we can, that an act seems best does not fully explain our doing it. For we can always reject what reason or our natures counsel.

For both intellectualists and voluntarists, God is 'absolutely' able to do whatever he is powerful enough to do, and 'ordinately' able to do just whatever he *would* do, given his character and covenants. For both, God is absolutely powerful enough to lie, but ordinately cannot do so. That God should lie is no contradiction. So God's omnipotence can effect it. But God would never actually lie. For intellectualists, this is because, as perfectly rational, God sees that lying is wrong and chooses accordingly. For voluntarists, God would not lie just because he has so chosen.

For Aquinas, all ten Commandments are necessary moral truths, which God sees and proclaims. For Scotus, necessarily, loving God is right and hating him wrong: as God is infinitely good, there can be no reason to prefer anything else to him, and so rational agents must love him above all. All other acts, though naturally good or bad (perfecting or destroying our nature), are right or wrong contingently, because God commands or prohibits them. Further, God sometimes revokes his contingent commands. Yet according to Scotus, this does not make morality arbitrary. God commands or prohibits acts due to their natural goodness or badness, which reason sees. God revokes precepts only rarely, where the values a law serves are better served by exception. For Scotus, God cannot command irrationally. So where God makes moral exceptions, these are rational; reason might anticipate his doing so. Even contingent moral laws are 'natural' in the sense of being accessible to reason.

Ockham held that only acts in accord with reason can be virtuous. But reason tells us that if there is one personal God, we should do as he says, and so reason tells us that both reason and a revelation by such a God can teach us what is right. Still, while both reason and revelation can teach right and wrong, only God's command *makes* acts right or wrong. God in fact commands only acts that accord with right reason. He need not have done so. For Ockham, only a superior's command can impose an obligation, and God has no superior: so God has no

obligations. Evil is acting counter to obligation. So according to Ockham, God cannot do evil. God in his absolute power can order fornication or theft. If he did so, these acts would be right. Even if God made Satan hate God, God would do no evil (as he has no obligation not to do this). Nor would Satan, as he would not control his own actions.

For Ockham, God can cause any creaturely effect unaided or block any creaturely cause. So even if a cause reliably yields an effect, the occurrence of one does not entail that of the other: causal connections are contingent. If so, a priori reasoning can tell little about real causal relations. Consequently, Ockhamist voluntarism was a prod to empiricism. Since it could in any case be God rather than a creature who produces an effect, voluntarism led too towards scepticism about created causality (see Nicholas of Autrecourt §2). Among the effects God can produce are apparent sensations of an object. So voluntarism insisted that what we seem to sense need not really be there, thus making God a remote ancestor of Descartes' deceiving demon (see Descartes, R. §4). The idea that only a will's command imposes obligations helped sow the seeds of legal positivism (see Legal positivism §§1-2). The voluntarist claim that God need not have accepted acts consonant with our nature or in our power as meritorious was a source of the Reformers' insistence that human salvation is wholly a matter of divine grace.

Voluntarism, Jewish

Voluntarism with respect to humanity and divinity became a powerful current in medieval Jewish philosophy, partly in response to the Neoplatonic doctrine of eternal and necessary emanation, which seemed to rob God of the freedom to create, and partly in response to predestinarianism. Solomon ibn Gabirol and Hasdai Crescas were among the Jewish philosophers whose metaphysics gave pride of place to the divine will over intellect, like medieval Christian voluntarists. For many other Jewish thinkers, the centrality of actions sets voluntarism firmly into the context of moral responsibility rather than of metaphysics. Predestinarian arguments like those of Abner of Burgos seemed to Jewish thinkers to rob human beings of moral responsibility. Among the typical defenders of Jewish voluntarism against these arguments was Abraham Bibago.

1 Will versus intellect

In Western Christianity, voluntarism has long been associated with the precedence of will over intellect in humanity and divinity. An early Jewish voluntarist in this sense, Ibn Gabirol, made the will the intermediary between God and the universal matter and form that anchor his ontology. In classical Neoplatonism, intellect, not will, was the first emanation in the divine production of the world. Crescas reacted against the Aristotelianism of Maimonides, much as Duns Scotus reacted against the Aristotelianism of Aquinas, by making will, not intellect, the basis of the affinity between God and humanity (see Crescas, H.; Maimonides, M.).

Ibn Gabirol and Crescas, however, had a limited impact on later Jewish philosophy. Ibn Gabirol did profoundly influence the Franciscan Augustinians, who knew him as Avicebrol or Avicebron and relied on him in laying the groundworks of later Christian voluntarism. His chief philosophic work, *Mekor Hayyim (Fountain of Life)*, survives intact only in Latin translation, *Fons Vitae*. In Jewish thought, only traces of his approach to foregrounding God’s will are found - in Kabbalah, in the work of Joseph ibn Tzaddik (d. 1149), and in the writings of the thirteenth-century philosopher-Kabbalist, Isaac ibn Latif (see Kabbalah). As for Crescas, his approach to this issue, for many later philosophers, was eclipsed by that of Maimonides.

Medieval Christian philosophers emphasized the will/intellect issue more than Jewish philosophers. Christianity is classically a religion of faith: inner states, beliefs and contemplation are foundational. Greek philosophy, especially Platonism, can place a similar emphasis on the inner life of the soul. This helps explain Augustine’s affinity for Platonism. For the Greeks, however, intellect was the dominant inner faculty: as rational animals, humans differ from other beasts in their powers of rational discrimination. Intellect is determinative for rational choice; will is the dynamic power. Socrates even spoke of knowledge as sufficient to determine choices. For St Paul and Augustine, by contrast, one might know the good and still not do it. Will rather than intellect seemed the dominant inner faculty.

In Judaism actions, not inner states, are the central goal. Religious commitment is expressed not by affirming dogmas but by fulfilling God’s commandments. Ancient Judaism has no creed, and questions about the dominance of will or reason were not central at the outset. But for actions to have moral value and to merit reward or punishment, they must be freely chosen. Freedom of choice, accordingly, was upheld by most Jewish thinkers, typically alongside a strong commitment to divine omnipotence.

In the early fourteenth century, freedom became a particularly vexed doctrinal issue when Abner of Burgos, who had converted to Christianity late in life (changing his name in the process to Alfonso de Valladolid), attacked the idea of human freedom, arguing that God’s omniscience and providence require all human acts to be determined. Seeking to preserve both human freedom and divine providence, Isaac Pollegar (also spelt as Pulgar) responded by proposing that, since the whole universe is one individual, God’s will joins with our own in the production of free human actions, much as the soul’s will joins with the nerves of the hand to move the finger. Moses Narboni also responded to Abner and defended free choice on Maimonidean lines. Over a century later, the determinism of Hasdai Crescas may still have reflected the influence of Abner.

2 Will as freedom

In Jewish philosophy voluntarism was typically a question of the nature of the will and its freedom. Aristotelians generally saw free choice in terms of rationality. But many thinkers put the emphasis on volition, especially in

regard to divine freedom. Maimonides, for instance, demarcated philosophers of the Aristotelian tradition from the adherents of the Torah by the commitment of the latter to the world's creation by God's free act - which we humans can construe only in terms of our idea of will.

Abraham Bibago (d. *c.* 1489), writing two decades before the expulsion of the Jews from Spain, begins *Derekh Emunah (The Way of the Faith)*, his book on divine providence and Jewish faith, with a disquisition on divine will and agency. Starting from an Aristotelian distinction, he describes voluntary agents as being conscious of their actions and being able to perform either of two contrary actions. A natural agent is unconscious of its action and can perform only one of two opposing actions essentially. Divine agency is obviously not natural: God is omniscient. Voluntary action, however, typically aims at a goal which the agent lacks, and lack, or deficiency, is impossible in God. Philosophers consequently posit a third kind of agency for God, conscious but performing only one of two opposing actions, and not in pursuit of a goal.

This doctrine harks back to Plotinus' imagery, in which the world proceeds from the One as light issues from the sun (see Plotinus §5). To many religious philosophers this doctrine seemed to say that God acts involuntarily. But Aristotle's conception of voluntary agency allowed the necessary agency of emanation to be called voluntary, since voluntary agency for Aristotle required only the absence of external compulsion and the presence of knowledge. With this in mind, Avicenna specified that God's agency in emanation was the sheer result of knowledge, and could therefore be called voluntary in Aristotle's sense. Will here becomes God's joy in the overflow of goodness that is in fact an inevitable consequence of that goodness. Maimonides judged such combining of necessity and will to be incoherent, but the philosophers most deeply committed to the Neoplatonic-Aristotelian synthesis continued to call necessary emanation voluntary.

Against these philosophers, Bibago argued that a God who acts by necessity would be just as deficient as a voluntary agent who has needs. Furthermore, a necessary cause must produce an effect similar to itself, as fire produces heat. Thus necessary agency does not explain how an infinite deity can produce a finite universe. Only voluntary agency, in Bibago's view, could solve this problem.

But if a voluntary agent lacks the end it intends, why would a voluntary God not be deficient? Bibago explains that ends can be either internal or external. Pursuit of an external end implies a deficiency in the pursuer. But God acts for an internal end, his own essence, and thus remains without deficiency.

3 Will versus necessity

The intellectualist necessitarianism that Bibago opposed was denounced by traditional philosophers and theologians in Christianity, Judaism and Islam. It was part of the so-called Latin Averroism condemned in 1277 by the Bishop of Paris (see Averroism, Jewish; Averroism). The most 'Averroist' of Jewish philosophers was Isaac Albalag (*fl.* thirteenth century), who translated into Hebrew al-Ghazali's *Maqasid al-falasifah (Intentions of the Philosophers)*, a summary of Avicenna's philosophy. Albalag was routinely attacked by traditional minded Jewish philosophers of the fifteenth century. He seems to be the target of Bibago's arguments against those who considered God an agent by necessity. The Averroist fusion of necessity and freedom forms the background for Spinoza's combination of liberty and necessity and helps explain the hostility of traditional Jews towards his philosophy (see Spinoza §4).

From a Christian perspective, perhaps because of Augustine's Platonic affinities, Neoplatonism has often been viewed as more congenial to religion than the Aristotelianism that came to dominate later medieval philosophy. For Jewish voluntarists, however, the threat to divine and human freedom seemed to come from Neoplatonic necessitarianism. The teleological perspective of Jewish voluntarism and its commitment to human freedom gave it an affinity to Aristotle, although Aristotle assigns no will to God and does not offer a theory about a faculty of free will.

The idea of a voluntary deity resonates with the biblical portrayal of God. For the voluntarists, what God and humans share, the divine image in humanity, is not simply the intellect but the spontaneity of freedom - not just an intellectual link but the possibility of personal dialogue. The spirit of Jewish voluntarism, understood in this vein, persists in the philosophy of dialogue pioneered in modern Judaism by Martin Buber and Franz Rosenzweig.

Von Wright, Georg Henrik (1916-)

G.H. von Wright is one of the most influential analytic philosophers of the twentieth century. Born in Helsinki, Finland, von Wright did his early work on logic, probability and induction under the influence of logical empiricism. In 1948-51 he served as Ludwig Wittgenstein's successor at Cambridge, but returned to his homeland and later became a member of the Academy of Finland. He did pioneering work on the new applications of logic: modal logic, deontic logic, the logic of norms and action, preference logic, tense logic, causality and determinism. In the 1970s his ideas about the explanation and understanding of human action helped to establish new links between the analytic tradition and Continental hermeneutics. Von Wright's later works, which are eloquent books and essays written originally in his two native languages (Swedish and Finnish), deal with issues of humanism and human welfare, history and future, technology and ecology.

Georg Henrik von Wright was born in Helsinki on 16 June 1916. The family, belonging to the Swedish-speaking minority in Finland, had moved from Scotland in around 1650. (Phonetically the name is pronounced as 'rigt' rather than 'rait'.) In 1934 von Wright began to study philosophy at the University of Helsinki under the supervision of Eino Kaila. Kaila, a charismatic teacher and cultural personality, was the Finnish associate to the Vienna Circle (see Vienna Circle). The young von Wright's studies in logic and philosophy of science in the spirit of logical empiricism led to his doctoral dissertation *The Logical Problem of Induction* in 1941. His main thesis is that Hume's problem is logically unsolvable: the demand for a justification of induction is self-contradictory. Von Wright later showed his expertise in probability theory and its history in a number of articles on subjective probability, randomness, paradoxes of confirmation and inductive logic. The most important of his contributions is *A Treatise on Induction and Probability* (1951), which carefully develops a system of eliminative induction in the tradition of Bacon and Mill by using the concepts of necessary and sufficient conditions.

In the spring of 1939 von Wright went to Cambridge to meet C.D. Broad, and was permitted to follow Ludwig Wittgenstein's lectures. Wittgenstein made a very strong personal impression on the young Finn. The contact and friendship was renewed after the war. Regular discussions with G.E. Moore also made an impact on his philosophical views. In 1948 von Wright was invited to become Wittgenstein's successor as Professor at Trinity College, Cambridge. After Wittgenstein's death in 1951 he decided to return to Helsinki, where already in 1946 he had been appointed the Swedish-language Professor of Philosophy. Together with Elizabeth Anscombe and Rush Rhees, von Wright became the executor and editor of Wittgenstein's posthumous works. The study, organization, systematization and publication of this exceptionally rich *Nachlass* was a lifelong task for him.

Von Wright's early work on philosophical logic discusses classical topics like predication, negation and entailment. The characterization of logical truth by means of the constituents of monadic predicate logic led his most renowned Finnish student Jaakko Hintikka to a general theory of distributive normal forms in 1953. In his Cambridge years von Wright became interested in the logical properties of various kinds of modalities: alethic (possible, impossible, necessary), deontic (permission, prohibition, obligation), epistemic (verified, undecided, falsified). In 1951 he published *An Essay in Modal Logic*, which studies in a syntactical way various deductive systems of modal logic. In the same year he published perhaps his most famous article, 'Deontic Logic', in *Mind*, which made him the founder of modern deontic logic. These works of philosophical logic had a profound influence on the direction of analytic philosophy - including action theory and the philosophy of law. Von Wright distinguishes technical oughts (means-ends relationships) from norms issued by a norm authority. The classical book *Norm and Action* (1963a) discusses philosophical problems concerning the existence of norms and the truth of normative statements; on these issues the author has often changed his mind. Von Wright's main work on meta-ethics and value theory is *The Varieties of Goodness* (1963b), which analyses different concepts of goodness. The two major works in 1963 established his position as a leading philosopher of his time.

In *Explanation and Understanding* (1971) von Wright turned to philosophical problems concerning the human and social sciences. He defends a manipulative view of causality, where the concept of action is primary to the concept of cause. He argues that human action cannot be explained causally by Hempel's covering law model, but has to be understood intentionally (see Hempel, C.G.). The basic model of intentionality is practical syllogism, which relates action by a sort of logical connection with wants and beliefs. This work, sometimes characterized as

anti-positivist analytical hermeneutics, has been regarded as an important bridge between analytic philosophy and the Continental tradition. Von Wright's studies in truth, knowledge, modality, lawlikeness, causality, determinism, norms and practical inference were published in 1983-4 as three-volume *Philosophical Papers*. The preparation of a volume in the Library of Living Philosophers was started in the early 1970s, but its publication was delayed until 1989.

In 1961 von Wright inherited Kaila's position as one of the twelve members of the Academy of Finland; this research professorship is the highest honour that Finland has given its most prominent scientists. Von Wright has written eloquent essays in Swedish and Finnish on the history of ideas and the philosophy of culture. In the 1950s he explored the philosophy of history (Tolstoi, Spengler) and myths about knowledge (Genesis, Faust). In his later work on humanism and the ethics of science, he became increasingly critical of the modern scientific-technological civilization, its narrowly instrumental concept of rationality, and its myth of progress. Von Wright's public pleas for peace and human rights, a better society and a more harmonious coexistence between human beings and nature have made him the most esteemed intellectual in the Scandinavian countries.

Vulnerability and finitude

Power has always been a central category of political thought and theory; its counterparts, powerlessness or vulnerability, and more generally finitude, have seemingly been much less discussed. Yet finitude has been a theme for many writers, particularly on metaphysical and epistemological topics, who emphasize that claims about human knowledge cannot presuppose that we command a God's-eye view of ourselves or the world; while vulnerability has been a theme in ethical and political philosophy, challenging idealized 'models of man' that take exaggerated views of human capacities and autonomy, and which overlook the mundane realities of dependence, poverty and frailty.

1 Finitude

Writing on finitude emphasizes that we can look at matters only from the vantage point of finite and fallible beings, of men rather than of angels. It criticizes some traditional metaphysical writing for taking divine omniscience and omnipotence, and other divine 'perfections', as models or standards of power, goodness and knowledge, for measuring human achievements by these yardsticks, and for concluding that human finitude is to be seen as (ineliminable) deficiency, lack or privation.

Such metaphysical writers - (Plato, Descartes and other rationalists are often cited as paradigms - see Rationalism) - assume that, finite as they are, human beings can form a conception of unlimited power and knowledge, and can understand their own limitations from that perspective. In doing so these writers take divine or infinite power, reason, goodness and knowledge as models for human performance - or rather lack of performance. Assumptions that human beings can appeal to powers of understanding and standards of perfection appropriate to an infinite being or to a transcendent vantage point have repeatedly been criticized. Yet many writers who have thought that they had successfully put aside appeals to transcendent, ideal standards have been accused by their successors of covertly reintroducing one or another variant of those very standards. For example, Kant (1781/1787) insists that he starts from the standpoint of *human* reason, but many of his critics have thought that he reinstates a God's-eye view of the world and human life, and in particular that his accounts of freedom and of ethics require him to do so (see Kant, I. §§9-11; Kantian ethics). Nietzsche and Heidegger both criticized Kant for this failing, and both aimed to put aside any appeal to a transcendent standpoint or to the knowledge and goodness of an infinite being; both have in their turn been criticized for tacit reliance on such a standpoint.

2 Vulnerability

In one way, writing in ethics must assume the possibility of human limitations: it would be pointless to propose norms or standards unless the possibility of failure to live up to them was acknowledged. However, much writing on ethics, while allowing for human failure, has invoked idealized conceptions of human rationality, knowledge and autonomy, or alternatively of human intimacy and affections, which are not achieved by many or even by any human beings (see Autonomy, ethical). Writing that is unrealistic in these ways can overlook the vulnerability of human lives and may then recommend action that takes too little account of others' vulnerabilities. Critics of various idealized conceptions of the human agent in ethics and political philosophy have emphasized a variety of ways in which people may be vulnerable. Some have stressed ways in which poverty limits action and capacities for action; others have pointed more generally to the fragility of human life, action and achievement; yet others have pointed to the fact that dependence on others is normal and far from being a form of moral failure may be a form of moral achievement.

There are then many ways in which writing on ethics can underestimate the significance of human vulnerability. For example, certain models of rational choice, and with them much utilitarian writing, assume idealized abilities to choose rationally, which are not in fact achievable by human beings: ordinary people may find such reasoning and the prescriptions it points to unconvincing (see Utilitarianism; Rationality, practical).

Some accounts of justice, in particular those favoured by libertarians, see justice as a matter only of according others like liberties (see Libertarianism). They deploy idealized views of human autonomy, by which others' needs and vulnerability are irrelevant to justice. Many other accounts of justice take some account of poverty and need (see Liberalism). They may, for example, argue for welfare systems that could protect people from these sources of

vulnerability, or for certain sorts of equality. Yet theories of justice often say little about vulnerability that arises from subordination or dependence on others, in particular about those that can arise from quite ordinary familial or gender relationships (see Family, ethics and the).

Some of these misleading idealizations have been challenged in feminist writing, in discussions of friendship, and in writing on the virtues (see Feminist ethics; Feminist political philosophy; Virtue ethics; Virtues and vices). A common criticism of all writing on justice is that it takes an idealized view of the autonomy of individuals or of citizens, forgetting that people are also linked in friendship and family, and that family relationships are often relationships of dependence, and so of power and of vulnerability. On the other hand, some of the proponents of friendship and virtue ethics, who acknowledge the moral importance of relationships and attachments, tend to take a rosy and even a falsely idealized view of the quality of close relationships, and thereby ignore the fact that vulnerabilities can be created and deepened by dependence. Feminist writers have often been more realistic about this range of vulnerabilities.

Vygotskii, Lev Semënovich (1896-1934)

Vygotskii was a Soviet psychologist, the most comprehensive in creative reach and the most influential. Trained in literary studies and originally active as a critic, he took a post in a pedagogical institute and came thus to psychological science, with a special interest in child development. That was the period of foundational debates between rival schools of psychology, intensified in the Russian case by the Revolution of 1917 and the subsequent campaign for a Marxist school. Vygotskii became the major theorist at the central Institute of Psychology. While dying of tuberculosis he worked his intensive way through contested claims to know what mind is and how it acts. His profuse reflections on that large contest remained largely unpublished for decades, while disciples echoed his call for a 'cultural-historical' approach to a unified science of the mind, and actually worked on the mental development of children and the neuropsychology of brain damage. The concept of 'activity', which was supposed to resolve philosophical issues, served largely to evade them, while harmonizing with Marxist-Leninist slogans on 'practice'. Among Western cognitive psychologists Vygotskii acquired a tardy reputation as a pioneer who emphasized social interaction in the mental development of children. The publication of his major works in the 1970s and 1980s revealed a much broader theorist. His central theme was the obvious truth at the basis of each artistic and psychological school, the lure of an effort to unify all of them, and the present impossibility of achieving such unification within science, outside philosophical speculation.

1 Life

Son of a bank officer in a provincial town of tsarist Russia, Vygotskii was given a secularized Jewish education until he entered Moscow University, where he studied language and literature. He was already publishing critical essays when he graduated in 1917, the year of the communist Revolution. Vygotskii returned to his home town, where he spent the years of civil war and economic collapse teaching in a secondary school and a pedagogical institute, adding child development and mental defect to literary art as crucial problems for claims to know what mind is and how it acts. A Marxist approach, increasingly demanded by the new government, provoked hostility among some psychologists, varied mixtures of Marxisms and psychologies among others, and an inclination in the ideological establishment to favour the reduction of mind to neural reflexes, as Pavlov and Bekhterev claimed to be doing. In 1924, at a conference devoted to the campaign for Marxism, Vygotskii's presentations struck the audience as a major event, the illumination of a way out of an impasse.

Bukharin, the Party's chief of ideology, had been commending 'reflexology', but the central Institute of Psychology had continued to set it aside as physiology, not psychology, which seeks to understand consciousness, not to explain it away. The founder of the Institute, G.I. Chelpanov, who rebuked the Party ideologists for misunderstanding both psychology and Marxism, had been replaced as director by K.N. Kornilov, who enthusiastically endorsed the Party's campaign, while continuing the kinds of research that he had learned from Chelpanov. The impending clash between the ideological establishment and the specialists in psychology was brilliantly finessed by Vygotskii. He praised Bukharin while bringing out the underlying clash between Pavlov and Marx, between the reduction of mind to conditioned reflexes and the analysis of mind as it expresses itself in 'cultural-historical' development.

He was appointed to the Institute of Psychology, where he became the most influential theorist by virtue of his astonishing breadth of knowledge, acute insight and critical appreciation for all the approaches to a contested discipline. That eclecticism, at odds with the drift in the ideological establishment towards an exclusive Marxism, was the probable reason why Vygotskii's major writings of the 1920s went unpublished. They circulated in manuscript, provoking discussion, attracting disciples in part, one supposes, by the sense of daring in his quiet dismissal of projects for a uniquely Marxist science. *Psikhologiia iskusstva (The Psychology of Art)* - awarded a doctorate in 1925, first published in 1965, heavily abridged - emphasized Marx's confession that enduring works of art did not fit within his scheme of evolving base and superstructure, and drew on 'formalist' aesthetics and on Freudian psychology, though both were disapproved of by the ideological establishment. *The Historical Meaning of the Psychological Crisis* - completed in 1927, unpublished until 1982 - used Marxism once again as an expression of the crisis more than a solution for it: each major school of psychology was founded on an obvious truth, and all together were an incoherent jumble. Marxism suggested a way to coherence only at the most abstract level of methodology, by proposing a 'cultural-historical' approach.

Condensed bits of these views were published during Vygotskii's lifetime in special studies and brief surveys, which can be confusing, for Vygotskii was conciliatory towards the ideological establishment. If it believed, for instance, that Pavlov had discovered the neural mechanism of mental activity, Vygotskii would endorse that view in some publications - such as a textbook or a celebratory survey of Soviet psychology - while elsewhere he showed that Pavlov's claim was at odds with neuroscience and with the *Gestalten* of mental activity. Such amiable segregation of viewpoints became extremely difficult after 1930, when vehement crude young men brought Stalin's 'great break' (*velikii perelom*) to higher learning as well as industry and agriculture. They required an aggressively Soviet philosophy and psychology, thoroughly hostile to 'bourgeois' or Western scholarship. Vygotskii still tried to be nice. He did not perform the odious ritual of 'self-criticism', for instance, for praising Piaget as the main source of his own work on child development. He published a translation of a major work by Piaget, prefaced by exaggerated disagreement - a common technique in the Stalin era for keeping foreign ideas before the public in spite of official disapproval.

The 'great break' brought insistence on practicality as well as exclusivity: science must prove its difference from 'bourgeois' pseudo-science by immediate service to 'the construction of socialism'. Vygotskii and his disciples responded in three ways: by emphasizing the pedagogical utility of their studies in child development, the therapeutic promise of their work in mental illness and brain damage, and most broadly the usefulness of their evolutionary vision in the 'cultural revolution', which they interpreted as a drive to modernize the primitive mentality of the masses. *Etiudy po istorii poredeniia: obez'iana, primitiv, rebënok (Studies in the History of Behavior: Ape, Primitive, Child),* a little survey that Vygotskii and Luria brought out in 1930, presented their version of 'the biogenetic law'. Ontogeny recapitulates phylogeny; the child's mental development repeats in brief the evolution from ape through primitive to civilized mentality. That was offered as an orienting vision for organizers of collective farms as well as teachers of lower-class children, but the establishment declared it an insufferable insult to the masses.

A field study of 1931 was especially offensive. The peasant mentality in Kazakhstan was found to be mired in 'situational thinking', ill prepared for universal rationality. Though unpublished, the study was angrily attacked in the press. Any effort at comparative analysis of different mentalities was implicitly disapproved, even one that might try, as Vygotskii and his colleagues did not, to take into account the shaping influence of class or status in the interaction of researcher and subjects. Group psychology was a field of intuitive expertise for master politicians and managers; they were not to be instructed by academics, not even psychologists preaching visions of a 'cultural-historical' Marxist discipline founded on 'the biogenetic law' of mental development.

Tuberculosis killed Vygotskii in 1934, while he and his school were being denounced as pseudo-Marxist imitators of 'bourgeois' or Western scholarship, along with all other schools of would-be Soviet psychology. Even in that time of the triumphant yahoo, Vygotskii had exceptional influence. V.N. Kolbanovskii, the militant communist who was installed as director of the Institute of Psychology with a mandate to 'Bolshevize' it, published a brief précis of Vygotskii's *Istoricheskii smysl psikhologicheskogo krizisa (The Historical Meaning of the Psychological Crisis)*, expressing the hope that this landmark book would soon appear. Disappointed in that hope, Kolbanovskii managed to bring out a little collection of Vygotskii's essays called *Myshlenie i rech' (Thinking and Speech)* (1934), called *Thought and Language* in the 1962 English translation.

In Russia and abroad that text shaped understanding of Vygotskii's psychology for so long that the limitations and misperceptions built into it may be incorrigible. The dying author, with some help from Kolbanovskii, fashioned the book to appease the establishment in a time of rampant Stalinism - for instance, by omitting his arguments against any claim of a uniquely Marxist science, and by including his exaggerated criticism of Piaget. Moreover, the surviving disciples shaped the dead man's legacy to fit their own agendas, avoiding a 'cultural-historical' approach as anything but a slogan for studies of child development. The recovery of Vygotskii's actual thought became a historical project, of little interest to most specialists in psychology, who prefer to work in their separate trends and ignore the rivals. Foundational debates over the opposed assumptions of diverse trends, which preoccupied the emergent discipline in the late nineteenth and early twentieth centuries, have come to be considered pointless excursions into useless philosophy. In academic practice that is what the separation of psychology from philosophy means: studied disregard for the implicit incoherence of rival trends in psychology. The transformation of Vygotskii's legacy is an especially ironic case in point.

2 Thought

Specialists in the cognitive development of children often distinguish Vygotskii's approach from Piaget's as a contrast between exogeny and endogeny, acquisition from without versus unfolding from within (see Piaget, J.; Cognitive development). That is, as most acknowledge, an oversimplified scheme, for interaction between the child and its external world, mediated by adults and other children, is essential to Piaget's approach as it is to Vygotskii's, or indeed to any analysis of action, thought and speech in their intertwined emergence, whether in phylogeny or ontogeny or both together. Piaget's landmark studies in that large field were fundamental to Vygotskii, as he repeatedly acknowledged. The correction that he offered was originally limited to the special problem of 'egocentric' speech. Very young children talk to themselves a lot, gradually ceasing by school age. Piaget interpreted this by analogy with autism; Vygotskii demurred. He argued that talking to oneself is the child's way of trying out patterns of speech - and thought and appropriate action - as learned from other people. When Piaget learned of that correction, many years later, he gratefully accepted it as 'a new hypothesis: that egocentric speech is the point of departure for the development of inner speech, which is found at a later stage of development, and that this interiorized language can serve both autistic ends and logical thinking' (1962: 7).

The important distinctiveness of Vygotskii's approach is implicit in Piaget's final phrase, his simple contrast between autism and 'logical thinking', his neglect of expressive thinking in the mind's connections with the world. Piaget came to the problem of childhood mental development from an original interest in biological science and in the standardization of intelligence tests, and wound up with a theory of evolutionary epistemology, oriented most of all towards the scientific or logical and analytical functions of thought and language. Vygotskii came to the would-be science of mind through literary studies, trying to understand aesthetic experience as a mode of cognition at odds with the scientific mode.

His first major work was a lengthy analysis of *Hamlet* that focused on the meaning of the play, as established by a cultural tradition endlessly absorbed and reshaped in the interacting minds of audiences, actors and writers, including critics as well as original authors. Set within that context Vygotskii's interpretation of *Hamlet* came down to a sense of tension between a traditional formula and a creative alteration of it. What the audience expects to see enacted on the stage - criminal outrage corrected by vengeful justice - is contradicted by what the author and actors actually present - random violence, insanity, vengeance dissolving into pointless deaths. Melodrama, a traditional formula for anxiety aroused and set to rest, is thus evoked and altered to create tragedy, an unsettling sense of life and death as a process that cannot be justified. Thus Vygotskii sets a problem for the would-be science of mind: how to explain the satisfaction that author-actors-audience jointly derive from artistic expression of a tragic meaning of life.

Vygotskii recalls the ancient explanation - catharsis - and rehearses some modern claims such as Freud's of scientific grounding for it. He criticizes Freud for a primitive understanding of 'the pleasure principle' at odds with 'the reality principle', and for other sloppinesses in mixing aesthetic understanding with claims of scientific explanation. But Vygotskii's deepest disagreement is with all contemporary schools of psychological science which rest on a dream of reducing subjective experience and cultural expression to nerve energies accumulating and discharging. Such explanatory reduction of mind to body would be irrelevant to knowledge of the mind in the sense of understanding, in this case, the meaning of *Hamlet*.

Vygotskii quotes Spinoza, confronting the fundamental anomaly as follows: 'Solely from the laws of nature considered as extended substance' one cannot 'deduce the causes of buildings, pictures, and things of that kind which are produced only by human art; nor would the human body, unless it were determined and led by the mind, be capable of building a single temple'. Since Vygotskii cannot find in modern science any way out of that dualism, *The Psychology of Art* begins and ends with Spinoza's metaphysical response: 'The objectors [to monism] cannot fix the limits of the body's power, or say what can be concluded from a consideration of its sole nature'. Intent on a monistic fusion of aesthetic understanding and psychological explanation, Vygotskii was sufficiently rigorous to acknowledge that the two types of inquiry are incoherent.

Specialists in cognitive psychology have paid scant attention to Vygotskii's emphasis on the problems that expressive thought presents for their discipline, though *Thought and Language*, the little book that most shaped their understanding of Vygotskii, comes back to such problems repeatedly. A crucial case in point is his distinction between *znachenie* and *smysl*, usually translated as 'meaning' and 'sense'. It might be less bewildering to say

logical meaning versus expressive meaning, the former acknowledging the law of identity, the latter deliberately violating it. Vygotskii offers a vivid example from a conversation that Dostoevskii overheard among six drunken men, who took delight in using a one-syllable obscene word for six different meanings, expressed by changing tone and gesture. (The fact that the word is still taboo in a respectable encyclopedia is further evidence of the difference between logical and expressive meaning.)

Vygotskii liked to recall Franz Brentano’s *Psychology from the Empirical Viewpoint* (1874), which boldly confronted the unscientific clutter of psycholog*ies*, and started two more schools (Gestalt and phenomenology) with its arguments for unification (see Brentano, F.C.; Gestalt psychology; Phenomenological movement). The gap that Brentano came to acknowledge between ’genetic’ and ’descriptive’ psychology, and the analogous distinction that several thinkers made between ’explanation’ and ’understanding’ as different modes of knowing ourselves, were major influences in Vygotskii’s brooding over psychology. So was William James’ review of 1892, ending with confidence in the future, though now ’there is no science,… only the hope of a science…. Something definite happens when to a certain brain-state a certain "sciousness" corresponds’ (see James, W.). By the 1920s, among psychologists who were unwilling to put on blinkers, to ignore the fragmentation of the would-be science and its separation from expressive understanding of the mind, James’ witty optimism had given way to gloomy talk of ’crisis’. Karl Bühler, most notably, was writing *Die Krise der Psychologie* about the same time that Vygotskii wrote *The Historical Meaning [smysl] of the Psychological Crisis*, which shares with other such ruminations the ironic fate of marking the end of an era by dreaming of a new one. Vygotskii’s dream was unique in its special attention to Marxism as well as the ’meaning [*smysl*] of the psychological crisis’ - in the sense of a crisis in ’the meaning of life’ as well as the would-be science of mind.

He disapproved of claims of a supposedly distinctive Marxist psychology, arguing that they confused three different realms of discourse: the fragmented discipline called psychology, the methodology that might transform it into a genuine science, and the most general methodology of knowledge as a whole. Marxism, in his view, was relevant only in discussion of that broadest realm. It could be transformed into concrete methodological principles for psychology only through protracted labour within the discipline, striving to overcome the war of schools. ’Our science will become Marxist to the degree that it will become true, scientific; and we will work precisely on that, its transformation into a true science, not on its agreement with Marx’s theory’.

His reading of ’Marx’s theory’ emphasized its ’cultural-historical’ vision of human development, including its insistence on a reciprocal relationship between understanding ourselves and changing ourselves, progressing thus towards authentic humanity in activity-cum-consciousness. ’Activity’ in this very long-term historical usage is so much broader than in psychological studies of a child’s ’activity’ that the word becomes a different concept. Inattention to that difference, which marked Soviet psychologists’ talk of ’activity’ after Vygotskii, deprived such talk of any deeper function than soothing the ideological establishment, which glorified ’practice’ in even looser, less meaningful ways.

When Vygotskii argued that the science of mind is inchoate, he recalled Trotsky’s observation that ’man is himself inchoate’ (*stikhiia*, elemental chaos, from Greek *stoicheia*). The socialist revolution would create a new authentic human being along with a new authentic science of psychology. When Vygotskii indulged in such talk, he was far closer than Trotsky or any other political leader of ’the Soviet experiment’ to explicit utopianism, with overtones of modernist absurdity:

> In the future society psychology will be in actuality the science of a new person [*chelovek*]. Without that perspective Marxism and the history of science would not be complete. But that science of the new person will still be psychology; we now hold in our hands the thread leading to it. Never mind that that psychology will resemble present-day psychology as little as - in Spinoza’s words - the constellation Canis resembles the dog, a barking animal.

(1982-4: vol. 1: 436)

That image - the would-be science of mind as a dog barking at the orderly splendour of the night sky - concluded Vygotskii’s *Historical Meaning of the Psychological Crisis*, projecting Spinozist faith in monism upon the incoherence of contemporary culture.

Vysheslavtsev, Boris Petrovich (1877-1954)

Boris Petrovich Vysheslavtsev, Russian idealist philosopher and religious thinker, was exiled from his homeland in 1922 because of his anti-Marxism (which he later elaborated in a full-fledged philosophical critique). In western Europe he became a leading figure in the Russian émigré philosophical community, lecturing and writing on questions of metaphysics, ethics, philosophical psychology and social philosophy. Vysheslavtsev was particularly noted for his study (begun in an early work on the ethics of Fichte) of the irrational as the sphere of human contact with the Absolute. Subsequently he developed this theme through the application of concepts of depth psychology to ethics and to the interpretation of Christian doctrine.

The son of a Moscow lawyer, Vysheslavtsev matriculated in 1895 in the Law Faculty of the University of Moscow, where his mentor was the eminent legal philosopher Pavel Novgorodtsev. After graduating in 1889 he worked for some years as an attorney before beginning postgraduate studies at the university. In 1908 he was sent abroad for two years to prepare himself for a professorship; he worked principally at Marburg, under the Neo-Kantians Hermann Cohen and Paul Natorp. Vysheslavtsev was awarded the doctorate by the University of Moscow and appointed to a position as docent there in 1914; three years later he was named professor in the Law Faculty. After his expulsion from Russia he went first to Berlin and in 1924 settled in Paris, where he became a professor at the Orthodox Theological Institute. During the Second World War he moved to Switzerland. He died in Geneva in October 1954.

Vysheslavtsev’s first major philosophical work was his doctoral dissertation, *Ėtika Fikhte (Fichte’s Ethics)* (1914). Although he was initially an orthodox proponent of Fichte’s transcendental idealism, in this book Vysheslavtsev presented an original interpretation of Fichte by concentrating on the role of the irrational and the concept of ‘the Absolute’ in the German thinker’s outlook. Arguing that philosophy is confronted with a basic antinomy between what he calls ‘system’ (rationality) and ‘infinity’ (irrationality), Vysheslavtsev affirmed that beyond every rational concept there is ‘the mysterious limitless’ - the infinity or Absolute that cannot be dealt with conceptually but is accessible only to intuition. Vysheslavtsev attempted to describe this irrational infinity by the use of concepts in the modern philosophy of mathematics, such as Cantor’s distinction between potential and actual infinities (see Cantor §1-2). But he concluded that no form of discursive, conceptual thinking is adequate to the task; although philosophy can show us the necessity of acknowledging the Absolute, philosophy cannot analyse it as Hegel sought to do in his metaphysics of Absolute Spirit.

In his efforts to explore this elusive realm, Vysheslavtsev in later works turned towards the study of religion, believing that the quest for the Absolute is the core of the religious attitude. In *Serdtse v khristianskoi i indiiskoi mistike (The Heart in Christian and Indian Mysticism)* (1929), he examined the biblical notion of ‘the heart’ as a fundamental non-rational human capacity; he found that ‘the heart’, in addition to being a source of mystical knowledge distinct from the knowledge gained by the intellect, is the fundamental ontological principle at the root of the human self as a loving and free being. He noted that both Christian and Hindu mystics affirm such an ontological principle, although they differ in their understanding of its relation to human individuality.

In his most important philosophical work, *Ėtika preobrazhennogo Ėrosa (The Ethics of Transfigured Eros)* (1931), Vysheslavtsev employed concepts of depth psychology to construct an ethical theory grounded in the irrational nature of human beings and their relation to the Absolute. Ethical ‘laws’ or imperatives as traditionally understood are ineffectual, Vysheslavtsev believed, because they are merely addressed to consciousness and rationality and do not engage the unconscious depths of instinctual human life; indeed, drawing on the work of the French psychologists Émile Coué and Charles Baudouin, he argued that such imperatives generate subconscious resistance in accordance with what he calls ‘the law of irrational opposition’. Christian ethics, in Vysheslavtsev’s view, pursues the correct approach to morality by presenting not legalistic commands but beautiful images of moral virtue in the persons of Christ and the saints; these images engender deep-seated responses of admiration and love, thereby transfiguring the irrational instincts and impulses (‘Eros’) that resist conscious control. In the spirit of Freud and Jung (he knew their works well), Vysheslavtsev called this moral transformation of basic instincts ‘sublimation’, and he saw in it the key to the understanding of the Christian moral life.

Sublimation, for Vysheslavtsev, is not a purely deterministic process subject to psychologistic explanation. It occurs only if the individual will has freely chosen the path of elevating and refining Eros and has enlisted the imagination in creating the needed images of moral virtue. Sublimation takes place, furthermore, only with the aid of divine grace; the individual spirit must be inspired from on high, by its vision of the Absolute as the fullness and perfection of being. This orientation towards the Absolute makes sublimation possible, but the divine grace that flows from it must still be freely accepted in order to be morally significant in the life of the individual. Thus in Vysheslavtsev's ethics of sublimation, both free will and grace are necessary but not sufficient conditions for the moral life. In their interaction free will is itself sublimated, being raised from its primitive state of arbitrariness to the condition of moral freedom.

The two books published by Vysheslavtsev in the last years of his life reflect the heightened interest in social issues that marked his thinking from the late 1930s, when he was also active in the ecumenical movement. *Krizis industrial'noi kul'tury (The Crisis of Industrial Culture)* (1953) is a work of social philosophy in which he rejects Marxism (and socialism generally) as a socioeconomic system and elaborates an alternative he calls 'neo-liberalism', which stresses the humanization of industrial culture through the widespread application of economic democracy. In *Filosofskaia nishcheta marksizma (The Philosophical Poverty of Marxism)* (written in the mid-1940s but not published until 1952), he presented a searching and philosophically sophisticated critique of the self-styled 'dialectical and historical materialism' then prevailing in the Soviet Union.

Wallace, Alfred Russel (1823-1913)

Co-discoverer with Charles Darwin of the theory of natural selection, Wallace travelled to the Amazon in 1848. Four years of collecting specimens there for sale in Europe revealed patterns of geographical distribution among animals. Unfortunately, much of his South American collection was lost in a fire at sea during the voyage home, which forced him to begin his collecting anew. This led to eight more years of travel (1854-62), this time in the Malay Archipelago, where he made his own momentous discovery of the theory of natural selection in 1858. An exceptionally clear thinker, he made many valuable contributions to evolutionary thought.

Wallace was a self-taught naturalist, as was his friend H.W. Bates, who accompanied him to South America. They read many of the books that Darwin read, thus sharing to some degree the same intellectual climate despite their plebeian background. Indeed, both Wallace and Darwin read T.R. Malthus on population, and both cited him as a major factor in their independent discoveries of the agency of natural selection. Wallace also read Darwin and C. Lyell, among others, Lyell being of special interest because Wallace cast him in the role of chief opponent as he developed his own thoughts during his travels in the Malay Archipelago, as recorded in his (unpublished) ‘Notebook’ (see Geology, philosophy of §1).

It was broadly believed in the 1850s that species were permanent, while varieties were not; rather, they were thought to be produced by ordinary generation and to vary only within strict limits. Species were somehow ’created’ in one or more centres of ‘special creation’, a term widely used, even by Wallace and Darwin, meaning to a zoologist, as Robert Owen remarked, ’a process he knows not what’. Wallace maintained that ’ every species has come into existence coincident both in time and space with a pre-existing closely allied species’ (1855). In his ’Note on the Theory of Permanent and Geographical Varieties’ (1858a), he asked, ’ why should a special act of creation be required to call into existence an organism differing only in degree from another which has been produced by existing laws?’. And, finally, there was the famous manuscript sent to Darwin in the spring of 1858. These three papers formed the foundation of Wallace’s theory of evolution by means of natural selection, his explanation of ’creation’, with natural selection as the agent of change. H. Spencer later suggested ’survival of the fittest’ as an alternative term for ’natural selection’, an idea accepted by both Wallace and Darwin.

Wallace’s manuscript reached Darwin on 18 June 1858. In an effort to protect Darwin’s priority, Lyell and J.D. Hooker worked out the immediate reading of Wallace’s paper before the Linnaean Society of London on 1 July, preceded by two contributions from Darwin. These three taken together are known as the ’joint papers’. Neither author was present. Darwin always maintained that their two theories were exactly alike, when in fact they differed markedly in detail. For example, Darwin relied heavily on data from domestic animals, while Wallace based his theory largely on data from wild animals. Only the concept was the same. Furthermore, over the years various errors regarding this event have crept into the record. Wallace and Darwin continued their fruitful correspondence, initiated by Wallace in October 1856, until just a year before Darwin’s death in 1882, as often as not disagreeing with one another in lively argument.

Attracted to the subject of geographical distribution during his travels in South America, Wallace became its leading authority, his work culminating in his *Geographical Distribution of Animals* in 1876: ’ The present work is an attempt to collect and summarize the existing information on the Distribution of Land Animals; and to explain the more remarkable and interesting of the facts, by means of established laws of physical and organic change’. This was supplemented four years later by *Island Life*. Basic to this development was the recognition of zoological regions, Wallace supporting the scheme proposed by P.L. Sclater in 1858. The sharp division between the Asian and Australian faunas found on either side of the strait separating the Indonesian islands of Bali and Lombok was named ’Wallace’s Line’ in his honour by T.H. Huxley.

When it came to human beings, Wallace partially abandoned natural selection. In 1864, in the first of several papers, he tried to show how humans could have been affected by natural selection, first in regard to physical form and then to the brain (also subject to natural selection) which took over control once sufficiently advanced, while the body remained essentially unchanged. Humans could easily make a warmer coat if necessary, once the mind had been developed, while an animal would have to go through the slow process of growing one, thus changing physically under pressure of natural selection. In *Darwinism* (1889), Wallace recognized a number of human

faculties - mathematical, musical, and so on, as well as knowledge of such fields as gravitation, chemical force, electricity - which he felt could not have been the results of natural selection but to belong rather to some spiritual world. This explains in part his interest in spiritualism, then a very popular but non-scientific pastime. In fact, a century later questions he raised in that connection have yet to be fully resolved. He disagreed with Darwin on the importance of sexual selection as the principal agent in human evolution, holding that sexual selection was merely a form of natural selection.

Wang Chong (AD 27-*c*.90)

The Han philosopher Wang Chong wrote a text called Lunheng (Disquisitions or Discourses Weighed in the Balance), one of the most exceptional and original documents in Chinese thought, compiled as it was during a crucial transitional period. Wang's main approach can be defined as a rational scepticism, questioning accepted history, the contents of canonical texts and philosophical claims about reality. His writings on fate develop ideas such as necessity, cause and uncertainty.

Wang Chong was born in Shangyu in the district of Kuaiji. His work, the *Lunheng (Disquisitions or Discourses Weighed in the Balance)*, composed of eighty-five chapters and more than two hundred thousand characters. Three themes pervade the text: a rational discussion on the nature of the classics (*jing*) (see Chinese Classics), his rational approach to nature and his original conception of fate (*ming*).

Wang Chong's intellectual context was the complex debate between the so-called New Text and Old Text schools, a discussion concerning the authenticity and interpretation of certain early texts. An example of his approach may be seen in Chapter 45 (On the Rain Sacrifice) of the *Lunheng*. Here, Wang asks on what do the texts base their affirmation that the rain sacrifice is necessary. In another example, in Chapter 23 (On Thunder), he asks if the destructive properties of thunderstorms actually reflect the 'anger of heaven'. He responds to the question by concluding that thunder is fire.

In questioning the ideal type of sage, the authority of the canonical texts and the practice of divination, Wang Chong adheres to the Old Text tradition, which emphasizes the creative nature of interpretation rather than a narrow scholasticism. In Chapter 14 (The Nature of Things), he states that Heaven did not create man on purpose. He makes it clear that there is no link between *ming* and virtue. One example he gives cites the careers of the favourite disciples of Confucius, Ran Boniu and Yan Hui, who were virtuous and scholarly but nevertheless died young. He believed in the injustice of Heaven, and gives many examples of the incapacity of Heaven to punish the guilty.

Wang's concept of fate is complex because it is linked with divination, cosmology and politics. He proposed three kinds of fate: natural destiny (*zhengming*), concomitant destiny (*suiming*) and adverse destiny (*zaoming*). The first refers to luck that results from original physical conditions; the second results from a combination of unpredictable coincidences; and the third signifies events that are contrary to expectations and opens up the possibility of contingency and the random factor. These approaches can be found in Chapter 3 of the *Lunheng*. This seems to be the most crucial and interesting chapter, especially as it concerns the ideas of necessity, cause and uncertainty.

The *Lunheng* is a text which belongs to the critical sources of Chinese culture, and it demonstrates that such sources are able to bring up original ideas and a new point of view concerning the Chinese world. Because of this text, we are aware that the Chinese world has many contradictory voices. There is not a static consensus in this debate, but a lively interplay of views among Chinese thinkers.

Wang Fuzhi (1619-92)

A seventeenth-century neo-Confucian and Ming loyalist, Wang Fuzhi is best known for his nationalism and his theories of historical and metaphysical change. His classical commentaries and other writings, not published until the nineteenth and twentieth centuries, present an exceptionally comprehensive and vigorously argued synthesis and critique of China's intellectual tradition. His ideas on topics such as politics, cosmology and knowledge have fascinated readers of widely differing philosophic persuasions.

Having but recently passed his first civil service examination when the Manchus invaded the Ming capital of Beijing in 1644, Wang Fuzhi (Wang Chuanshan) defied the new Qing dynasty, at first militarily and politically, then with his pen through more than forty years of relative reclusion. The secrecy of his writings accounts for their preservation until their publication in the nineteenth and twentieth centuries. It also explains his overdue recognition as one of China's best thinkers. The sense of political crisis underlying his writing attracts the interest of Chinese Marxists and non-Marxists alike.

More philosophically significant in this regard is Wang's cosmology and metaphysics, traced by him to the Song philosopher Zhang Zai but also historically connected to late Ming trends. Wang's work is based on the dynamic concept of *qi* (material force, literally breath) (see Qi). His practical emphasis on *qi* as opposed to *li* (principle) lends itself to a materialist interpretation particularly when linked with Wang's claim that the world consists of concrete things (see Li). However, the importance of *qi* is that it is self-moving and not predetermined from without, yet so constituted that its activity necessarily tends to produce order. This, together with mentalistic descriptions of *qi*'s activity, suggests an expressive cosmology akin to Wang's view of poetic expression. His mode of thought is organicist, which is partly why it is difficult to classify in idealist-materialist terms.

Wang's epistemology and ethical psychology are shaped by an awareness of non-Confucian systems. He opposes the extreme scepticism of the Daoists and Buddhists, but a dash of Chinese empiricism, together with his belief in the ultimate unfathomability of the non-human cosmos, makes him sharply critical of tidy, predictive systems such as those offered by numerology or Western science. Mind and senses work together to produce knowledge, but the mind comes into its own in the development of a 'synthetic a priori' type of moral knowledge through a mixture of intuition and reflection (also represented as the unfolding of *qi*). This kind of knowledge is based on moral experience and leads to moral practice (see Knowledge, concept of). Supporting Wang's ethical epistemology is an original and dynamic view of human nature as a perpetually renewed source and product of moral cultivation (see Xing).

Wang's organic conception of *qi* lends originality to his philosophy of history. In place of the common Confucian nostalgia for the 'feudal' past, Wang credits the historical process with its own natural trends and rationale (*li*). He even sees the possibility of other civilizations replacing that of the Chinese. However, this theoretic detachment does not extend to tolerance of foreign conquest in his own time. Wang Fuzhi's nationalism comes closer to racism than does normal Confucian ethnocentrism. Though passionately felt, it stands in uneasy relation to the philosophy which it ironically helped to inspire.

Good bibliography.)

Wang Yangming (1472-1529)

Wang Yangming was an influential Confucian thinker in sixteenth-century China who, like other Confucian thinkers, emphasized social and political responsibilities and regarded cultivation of the self as the basis for fulfilling such responsibilities. While sometimes drawing on ideas and metaphors from Daoism and Chan Buddhism, he criticized these schools for their neglect of family ties and social relations. And, in opposition to a version of Confucianism which emphasized learning, he advocated directly attending to the mind in the process of self-cultivation.

Having gone through a series of political ups and downs, Wang Yangming was acutely aware of the political degeneration and moral decay of his times. The influential teachings of Zhu Xi no longer offered a solution to such problems, the study of classics emphasized by Zhu having degenerated into a tool for social advancement, resulting in habits of memorization and fragmentary studies. Wang, who in his youth studied Zhu's teachings, developed a new version of Confucian thought, the main ideas of which are contained in the *Quanxilu (Instructions for Practical Living)* a collection of conversations and letters compiled by Wang's disciples, as well as in other essays and poems.

According to Zhu Xi, the mind already knows principle (or pattern); in relation to human lives, principle constitutes the realm of the ethical (see Li). In the original state, the mind's knowledge of principle guides and is sufficient for ethical action, but such knowledge can be obscured by distortive factors of the mind often referred to as selfish desires. 'Investigation of things' and 'extension of knowledge', two steps in a self-cultivation process described in a Confucian classic, are interpreted to mean arriving at the principle in things (via the study of classics and examination of daily affairs) so as to expand one's knowledge of principle, thereby regaining the knowledge one originally has (see Self-cultivation in Chinese philosophy).

While Wang also believed that everyone has 'innate knowledge' which can be obscured by selfish desires, he regarded innate knowledge not as prior knowledge of principle but as a disposition to respond to particular situations in appropriate ways without guidance from such prior knowledge. Principle is revealed in the responses of the mind when unobscured, and 'mind is principle' in the sense that principle does not exist independently of such responses. Furthermore, while such responses may involve some kind of knowing, there is a 'unity of knowledge and action' in the sense that the responses also involve motivations to act which are not explained by the knowing and which are sufficient for action (see Action).

Given his view that principle resides just in the responses of the mind when unobscured, Wang regarded Zhu Xi's emphasis on learning as misguided. He interpreted 'investigation of things' and 'extension of knowledge' to mean correcting what is incorrect in the activity of the mind so as to allow innate knowledge to reach out. That is, a main task of self-cultivation is constantly to watch for and eliminate selfish desires, until the mind is purified and selfish desires no longer arise. While de-emphasizing learning, he did not totally reject it since studying the classics can help one understand one's mind, and since there are details such as institutional arrangements that innate knowledge may tell one to learn.

Other interesting ideas of Wang's include his conception of the myriad things as forming 'one body'; that different things are linked is seen from the way plants and animals nourish human beings or the way herbs cure disease. Thus, ideally, one should be sensitive to the well-being of all things. Another idea is his view that things do not exist outside of the mind, an idea sometimes interpreted as a form of idealism (see Idealism). It is possible, though, that 'things' in this context refers to what forms a meaningful structure, so that what is at issue is not an ontological thesis but an observation about how the mind's awareness contributes to objects forming a meaningful structure for humans (see Awareness in Indian thought).

Another well-known idea of Wang's is his 'Four Sentence Teaching', which describes (1) what is without good and evil as the substance of the mind, (2) what is with good and evil as the movement of intent (the starting point of the mind's activity), (3) what knows good and evil as innate knowledge, and (4) what does good and eliminates evil as the investigation of things. Since principle, and correspondingly the distinction between good and evil, resides ultimately in the responses of innate knowledge ('mind is principle'), there is a sense in which innate

knowledge, which Wang identified with the substance of the mind, cannot itself be described as good or evil. Furthermore, innate knowledge is without good and evil in the further sense that, when responding to situations, it is not guided by thoughts of doing good or avoiding evil (‘unity of knowledge and action’). As for the second sentence, it describes how, when the mind is activated, intent arises and can point in a good or evil direction because of the distortive effects of selfish desires. The third sentence concerns how, despite such distortive effects, innate knowledge can still distinguish between good and evil, while the fourth sentence explains the investigation of things in terms of doing good and eliminating selfish desires so as to restore the original state of the mind. On this interpretation of the teaching, self-cultivation is a gradual process of persistently doing good and eliminating evil.

However, if it is innate knowledge that enables one to recognize selfish desires as problematic, then, since innate knowledge operates without guidance from a conception of good and evil, it seems that the elimination of selfish desires should also be a spontaneous process not requiring effort. That is, as soon as innate knowledge is brought to bear on things, all incorrect elements get corrected and one achieves sagehood without any need for persistent efforts to do good and eliminate evil. These two views represent a disagreement among disciples which Wang addressed by proposing that the two views capture two teachings, directed respectively to the ordinary people and to those of sharp intelligence. Subsequently, such disagreement led to divergent developments of Wang’s teachings by later followers.

War and peace, philosophy of

The war/peace dichotomy is a recurrent one in human thought and the range of experience it interprets is vast. Images of war and peace permeate religion, literature and art. Wars, battles, pacts and covenants appear as outcomes and antecedents in historical narratives. Recurrent patterns of warlike and pacific behaviour invite scientific explanations in terms of underlying biological, psychological or economic processes. War and peace are also often matters of practical concern, predicaments or opportunities that call for individual or collective action. While philosophers have explored all these ways of looking at war and peace, they have paid most attention to the practical aspects of the subject, making it part of moral and political philosophy.

Practical concern with war and peace can go in either of two main directions, one focusing on war and the other on peace. Those who doubt that war can be abolished naturally worry about how it can be regulated. So long as war is possible, there will be principles for waging it. Whether such principles should limit war-making to ends like self-defence or leave the choice to the discretion of political and military leaders is a matter of continuing dispute. Nor is there agreement regarding restrictions on the conduct of war, some holding that belligerents need only avoid disproportionate damage, others that it is morally wrong to harm innocents (for example, noncombatants). In situations of emergency both limits may give way, and moralists have debated whether this relaxation of standards is defensible. Disputes over the principles governing war raise difficult questions about action, intention and the character of morality itself.

If we think that wars can be prevented, it becomes important to focus on the conditions of permanent peace. Some who do this conclude that peace depends on the conversion of individuals to an ethic of nonviolence, others that it requires strengthening the rule of law. According to a powerful version of the latter argument, the absence of law creates a condition in which persons and communities are at liberty to invade one another: a condition that, in Hobbes's classic metaphor, is a 'state of nature' which is also a perpetual state of war. While treaties of peace may terminate particular wars, only political institutions that establish the rule of law within and between communities can provide security and guarantee peace.

1 War and peace as ideas

War can be conceived in many ways. For some it is a metaphor for all that is violent, destructive and lawless. The realm outside the world of Islam, for example, is thought of by Muslims as 'the house of war', a realm of unbelief and strife. General Sherman's idea that 'war is hell' exploits the Christian idea of hell as a domain of radical disorder (Pandemonium) as well as of fire and torment. War can also stand for the clash of opposites from which (as Heraclitus taught) all things spring. For Clausewitz, war is a self-driven process having its own principles of order. And war may be understood as a social practice or institution that takes different forms over time or in different cultures. Understood as organized armed combat, war may be distinguished both from lawless violence and from other kinds of force and coercion (see Coercion; Violence). 'War', in short, is a kind of order as well as disorder.

Similar dichotomies mark conceptions of peace. 'Peace' can mean either a temporary suspension of hostilities (a truce) or a permanent condition of tranquillity in which war is no longer feared. Where war is identified with lawlessness, peace becomes not the mere absence of fighting but a secure condition of mutual cooperation between individuals within a community or between communities. The idea that peace depends on legal order is a recurrent theme of Western political philosophy, one stated eloquently by Thomas Hobbes in *Leviathan* (1651) (see Hobbes, T. §7).

Hobbes identifies war with the condition of humanity in the absence of civil order - a condition of nature in which each human being has a right to all things. The state of war is the opposite of the civil condition, and avoiding its inconveniences is the chief motive for seeking peace. War is the natural consequence of a disposition to fight that exists wherever there is no guarantee of peace. Peace requires assurance that one will not be forced to fight, and this is possible only in the civil condition. Peace is a state of affairs that emerges not from the kind of agreement that terminates a particular war, but from an agreement creating a permanent legal order with civil institutions to declare and administer its laws (see §5).

On this view, peace is disrupted not by the lawful use of armed force, but only by the use of force contrary to law. The postulated antithesis between war and law must be seen not only in causal terms but conceptually: not only is law needed to secure the conditions that lead to war, but ‘war’ *means* the abrogation of lawfulness. One cannot hold that people are obliged by law to respect one another’s rights and at the same time that they are free to attack one another at will.

The premise of most political philosophy is that war is an evil to be escaped or at least regulated. But some philosophers, like Machiavelli (§4) and Nietzsche, have considered war a good rather than an evil. It may be a field for the display of virtues like courage, virtues which are quite different from those urged by Jesus in the Sermon on the Mount, or a way of cleansing the corruption of a decadent civilization, thereby recovering the greatness of former times or developing unrealized human potentialities.

For other philosophers, war must be understood before it is judged. It calls for philosophical investigation because it is an aspect of experience, a part of reality. In one version of this approach (illustrated by J. Glenn Gray in *The Warriors* (1959)), war is understood phenomenologically by considering how it appears to those who experience it. In another, the study of war takes a scientific turn as the philosopher seeks to identify the ‘causes of war’ in human nature, in the character of different states or in the structure of the international system. The concept of innate human aggression, the hypothesis that ‘liberal’ states do not fight wars with one another and the argument that war is an inevitable consequence of a decentralized international order illustrate explanatory theories at each of these levels.

2 Grounds for war

Although the philosophical justification of war predates the modern states system, the problem of justification is most easily introduced in this setting. According to what might be called the ‘political realist’ point of view, there is in the international system no authority superior to that of the separate states. Force may be used by governments to uphold their own internal law, but there is no international law that it properly upholds (see International relations, philosophy of §2). War is an instrument of foreign policy and its use is restrained only by prudence, not justice. It follows that there can be no distinction between just and unjust wars. States may agree for prudential reasons to restrict the use of force but obligations thus incurred can be overridden by ‘reasons of state’; that is, by considerations of national security. Where vital interests are at stake, states remain free to violate their agreements, acting in ways that non-realists might deem ‘unjust’.

The alternative view is that one *can* distinguish lawful and unlawful uses of force between states, that is, distinguish just from unjust wars. Although this has long been a part of the tradition of Catholic natural law, this view has had many non-Catholic interpreters, from Grotius to Michael Walzer, and is thoroughly embedded in international law. An unjust war does not merely interrupt peace (understood as a condition of calm marked by the absence of fighting), it violates the lawful order that guarantees states their independence and territory. An unjust war is not a brute fact but a wrong, and as such it justifies the use of force by other states to resist and punish it.

Underlying the distinction between just and unjust wars is the assumption that there is a society of states comparable to the community of individuals that comprise a single state. In place of laws made and applied by sovereign authority, the laws of the international community rest on international custom and natural justice. Although the international order is more uncertain than that which prevails within a peaceful state, only if we presume such an order can we distinguish just (lawful) and unjust (unlawful) wars (see Justice, international §1-2). In the same way that the rule of law in civil society protects the liberty and security of each citizen, the rule of law in international society protects the political independence and territorial integrity of each state. A state that violates these principles makes itself liable to action by other states, acting singly or together, to protect their rights and defend the principles on which international order rests. Unlike a citizen, a state may fall back on self-help because there is no superior power on which it can rely.

The idea of just war may be seen as a middle position between realist and holy war conceptions. For political realists, any war a state chooses to fight to protect its security is justified. But because security can be threatened by the mere power of other states as well as their conduct, realist reasoning can be used to rationalize aggression. For holy warriors (and their secular imitators), in contrast, it is the imperative to disseminate the faith that justifies

attacking others and, often, subjugating, converting, expelling or exterminating them. If we understand war to be an instrument of human will to secure justice, a just war must be distinguished both from self-preservation and from the promotion of a religious or ideological cause.

Although it is agreed in the just-war tradition that a war must be fought for 'just cause', there is dispute about which grounds for war meet this criterion. According to Aquinas (§13), a just war is neither a war of conquest nor a war of self-defence. It is a war in which another community is attacked for refusing to redress wrongs inflicted by its members or to restore goods or territory it has unjustly seized (Aquinas 1266-73: II, 2, q.40, a.1). The United Nations Charter, in contrast, limits the grounds for war by states to self-defence. But such a limitation, taken literally, would forbid assisting another state to resist attack. It would also forbid armed intervention within another state to end abuses by its government, for a government can mistreat its own subjects without attacking other states - a fact international law now recognizes and tries to prevent by distinguishing crimes against humanity from the crime of aggressive war. If a just war is one that redresses wrongs, the crimes of a government against its own subjects (today understood as violations of their 'human rights') may be included among these wrongs and therefore among the lawful grounds for war.

A much-debated question is whether war can justly punish, as well as resist, wrongs committed by other states. Some argue that states may resist aggression but not punish it. Punishment must be licensed by an international authority, and there is no such authority. Others reply that if states are not authorized to punish wrongdoing, it is hard to see how they can be authorized to resist it, either. Yet both might agree that waging punitive war against entire communities, long sanctioned by moralists as well as by state practice, rests on unacceptable views of collective responsibility. The practice of reprisals, however, continues to be justified by some moralists as a deterrent to further wrongdoing.

Other considerations besides 'just cause' may be offered for judging decisions to initiate a war. Aquinas, for example, argues that war cannot be justly chosen, even by those whose cause is just, unless that choice has been authorized by a ruler: 'private wars' cannot be just. This constraint does not limit the wars of sovereigns against one another, however, unless there is a higher authority to whom they are subject. Today the United Nations claims such authority. Although the Charter prohibits the unilateral use of force by states except in self-defence against armed attack, the Security Council may authorize collective military action to rectify a variety of other wrongs.

Aquinas also repeats the judgment of Augustine, that those who choose war must do so to resist wrongdoing and secure peace, not for the sake of vengeance or to gain power. In other words, the intention with which one fights, like the act of fighting itself, must meet a moral test. On one view of intention, to intend is to choose and thus to act. But we can further distinguish between intentions (what is aimed at) and motives (the state of mind or 'spirit' in which one acts). Some in the just-war tradition argue that intentions are always morally relevant, even if motives are not. For them, a war justified by the 'cause' of reversing an unjust conquest (like the Iraqi conquest of Kuwait) but one which is really intended to achieve some less defensible end (like permanently weakening Iraq) must be deemed unjust, as must one carried out in a spirit of hatred or cynicism. For political realists, in contrast, neither intentions nor motives count for much.

Because wars can occur within as well as between communities, moralists have asked whether there can be just civil wars. Under what circumstances are revolutions or wars of national liberation justified? When is it proper to overthrow a tyrant or usurper, or to resist a government when it demands the performance of immoral acts like participation in genocide or service in an unjust war? How, if at all, can terrorist acts against a regime be defended? Is morally-justified resistance to authority limited to various forms of noncooperation, including conscientious objection? Although just-war and pacifist ideas are clearly relevant to these questions, answering them also raises questions about political authority and obligation (see Civil disobedience; Revolution).

3 Conduct of war

Just wars are defined not only by the ends for which they can be fought but by the means used to fight them. If war is a practice, it has rules. Of these, rules restricting the targets that can be attacked are more basic, morally speaking, than those restricting the use of particular weapons or techniques like napalm or area bombing. Some moralists argue that the rules of war are adequately summed up in the principle that the harm inflicted by military

operations should be ‘necessary’ for and ‘proportionate’ to the ends sought, others insist that attacks on persons or objects not involved in fighting are wrong for reasons unrelated to these expediential considerations. Such attacks are wrong because they violate a fundamental prohibition against harming the innocent or their possessions.

This further restriction on the conduct of war is often stated as the proposition that persons who fight must not intend, either as an end or a means, the deaths of those not directly involved in the fighting. Waging war in ways that fail to discriminate between combatants and noncombatants is morally forbidden. In the classic vocabulary of natural law, those who are not engaged in fighting are ‘innocent’ (from Latin *nocens*, engaged in harmful activity). Innocents may not be attacked ‘intentionally’, although no wrong is done if they are harmed incidentally, as a foreseeable but unavoidable side-effect of permissible military action. According to the principle of ‘double effect’, acts that harm innocents may be justified if such harm cannot be avoided in pursuing a morally permissible end and the level of such harm is not disproportionate. One question in calculating proportionality is whether one should consider impartially the interests of everyone affected by an act, as both natural lawyers and many consequentialists argue, or should favour the interests of one’s own soldiers and civilians, as political realists hold. A more difficult issue is whether the distinction between the intended and unintended effects of an act is philosophically coherent (see Double effect, principle of).

An even stricter position is that one is barred from intending the deaths of combatants as well as noncombatants. One may seek to thwart an attack, but in doing so one must use no more than the minimum force needed. Here, too, the double effect principle may be invoked to distinguish permissible from impermissible harm. That one can foresee the deaths of enemy soldiers whose attack one is resisting does not mean that one intends their deaths, provided that in resisting one is choosing only to repel the attack, and that the foreseen deaths are the unavoidable consequence of using the only means of resistance available.

Should moral limits on the conduct of war be ignored if the stakes are high enough? If a country is about to be overrun by a genocidal adversary, many think that the victim may use any means to defeat the conqueror. Moral constraints that hold in ordinary situations are not binding in situations of extremity. This view reverses the usual structure of just-war argument: thus, although under normal circumstances moral principles constrain consequentialist calculations, when catastrophe threatens such calculations may be substituted for reliance on moral principle. There is an escape clause in cases of authentic necessity.

Most natural law and Kantian theories of morality reject the argument from extremity. In situations of communal emergency one might justifiably waive rules based on mere custom or utility. But one may not violate the exceptionless precepts of the moral law, like those forbidding aggression or the deliberate killing of innocents. For these reflect the basic principle (sometimes called ‘St Paul’s principle’) that evil may not be done for the sake of good. To permit such acts is to hold that a moral community can survive by measures that its own traditions condemn as immoral. In abandoning its principles, the community would be trying to preserve the lives of its members while denying the principles that define its integrity as a community. This problem does not arise for political realism, which treats all rules as merely conventional and instrumental. Realism assumes that a community can temporarily transgress its moral principles without changing its character as that community.

The argument from extremity plays an important part in the debate over nuclear deterrence. In so far as it targets civilians, and thus intentionally threatens innocents, a nuclear retaliatory strategy is not easily reconciled with ordinary moral ideas. It is sometimes argued that the deterrent is not immoral because it only threatens, but does not actually destroy, innocent lives. But if (see §2 above) intentions are themselves actions - if they involve choices and commitments, can determine the character of the chooser and can have a variety of consequences - it can be wrong to intend what it is wrong to do (the ‘wrongful intentions principle’). Unless it is just a bluff, the deterrent threat expresses an intention to do wrong under certain conditions and is therefore morally objectionable. It is doubtful whether such stratagems as counterforce targeting or the mere possession of nuclear weapons can justify nuclear deterrence under ordinary moral principles. The claim that the nuclear predicament creates a (permanent) state of emergency, which therefore necessitates the deterrent threat, is yet another way of attempting such a justification.

4 Pacifism and nonviolence

Because those who condemn war do so on many grounds, there are many different kinds of ‘pacifism’. Some

pacifisms are personal (it is morally wrong for me to fight), others general (no-one may fight). Some object to organized war, others to killing human beings, still others to killing any living creature or to any use of force whatsoever. In each case, war is opposed as a matter of moral principle.

But the label ‘pacifist’ is also applied to the position of those who, like Mahatma Gandhi or Martin Luther King, Jr, urge nonviolent resistance on pragmatic as well as moral grounds. Arguing that power rests on acquiescence, its advocates contend that tyranny and aggression can be resisted without armed force (although not without a kind of nonviolent coercion). Nonviolent resistance can range from militant noncooperation (like Sorel’s general strike) to the practice of ‘living in truth’ followed by dissidents in communist eastern Europe during the 1980s.

So-called nuclear pacifism, which objects to war involving nuclear but not conventional weapons, would seem to follow from just-war or perhaps even realist premises rather than from a principled objection to war as such. What is to be abolished is not war itself but a weapon that makes war too terrible to fight. More radical are movements that seek to abolish war by getting rid of war-causing social or political institutions (capitalism, the military-industrial complex, patriarchy) or by reforming the international order (through promoting free trade, collective security or world government).

Christian pacifism rejects war as an instrument of human purposes while recognizing it as a recurrent situation in which Christians must bear witness to their faith, serve others and search for nonviolent ways of dealing with a hostile world. Pacifism of this kind is an interpretation of the meaning of a religious faith. Like the early Christianity from which it takes its guidance, it focuses on creating a community of believers committed to living their lives together according to Christian principles. There are Christian pacifists like Tolstoi who see government as intrinsically violent and who therefore incline to anarchism: to govern is necessarily to act evilly, like Caiaphas, for the common good. Although often branded as ‘sectarian’ for turning away from the world, Christian pacifism can be missionary, concerned with transforming the world.

Pacifists attempt to seize the moral high ground, charging not only realists but just-war moralists with a myopic acceptance of the existing world and lack of faith in the possibility of social transformation. They also accuse those who believe war can be justified of presuming, against the evidence, that force is more effective than nonviolent action. In so far as the issue is whether morality permits war in some circumstances, pacifists are engaged in debate with those committed to the just-war idea. But if the issue is whether morality applies to war at all, pacifists find themselves allied with just warriors against political realists and others for whom morality is circumscribed by prudence. And in invoking necessity, even realists make clear their aversion to war, thereby taking sides with the just warrior and the pacifist against those who celebrate war as a good in itself.

5 Peace as an institution

For many philosophers, peace is an aspect of legal order. But what kind of legal order? For law can be a tool of domination and oppression, a form of war by other means - as Augustine was not the first nor Foucault the last to observe. Any legal order that can establish and guarantee peace acknowledges the subjectivity (and therefore the personality, freedom and human rights) of those who belong to it. So-called ‘martial law’, which is really a suspension of law, is an expedient rationalized as necessary to restore legal order. It is not the foundation on which permanent peace, an ordered tranquillity, can be constructed.

It is sometimes argued that although peace based on law can be enjoyed by portions of humanity (if states can be established), such peace is not possible for the world as a whole. Hegel argued that a world state is inconceivable because the existence of one state implies the existence of others: ‘without relations with other states, the state can no more be an actual individual than an individual can be an actual person without a relationship with other persons’ (1821: §331). The state therefore cannot exist alone; it needs other states to accord it recognition and give it an identity. But a state might acquire an identity in resisting other associations: pirates, terrorists or insurgents, for example. The idea of a world state is different from that of a state among states, but it does not follow that a single law-making authority for all humanity is inconceivable.

Others perceive not logical but practical difficulties: a world state would be ungovernable or likely to suppress human diversity and freedom. For Kant (§10), a world state is conceivable but would pass through despotism back to anarchy. For Hobbes, a world state is conceivable but unnecessary because adequate security can be enjoyed in much smaller associations: the state of nature that exists between sovereign states is not nearly as bad as that

which exists among individuals in the absence of civil order.

Both these conclusions may seem doubtful, however. If it is the fear of war that motivates individuals to accept political authority, one can imagine circumstances in which this fear is better escaped by creating a single world state, which would abolish war between states, than by creating many states, which can only perpetuate war. This argument becomes more persuasive as war becomes more dangerous. If, in contrast, states can coexist without threatening the lives or prosperity of their members, then individuals cannot be rationally motivated to establish a world state. But this second line of argument seems to undermine the case for any state. If states can coexist in a condition of nature, why cannot individuals or voluntary associations of individuals do the same? If the state of nature is tolerable for sovereigns then, under some imaginable circumstances, it may be tolerable for others. Even though its inconveniences may be greater, it does not follow that these must be so great as to necessitate sovereignty.

Although he thinks a world state would endanger rather than secure perpetual peace, Kant (1795) insists on the moral necessity of establishing a global legal order by means of a contract among independent states, for the rule of law among states both depends upon and reinforces the rule of law within each state. If peace depends on legal order, it must be ‘formally instituted’ by means of a constitution, internationally as well as internally. But the order established by the international constitution is confederal rather than unitary. The crucial elements of this constitution are: (1) that every state shall have a ‘republican’ constitution - that is, one that makes government the common business (*res publica*) of the people, and ensures that it is conducted according to law; and (2) that the international order must be a federation of republican states, not a world state. The first condition means not that each state must be a democracy, for democracies can be despotic, but that each should be governed by the rule of law; for Kant, this means separating the legislative and executive powers. If there is to be an international order based on just laws, each state must conduct its internal as well as external affairs on the basis of such laws. The second condition (federation) demands that even republican states give up their liberty to make war. If states do not yield this sovereign prerogative, they remain in a state of nature. To establish permanent peace, they must renounce not only the means of war (for example, standing armies) but the right of war. The new power to which they surrender this right must be a federation of republics.

Kant’s argument, then, is that to secure permanent peace, states must first agree to acknowledge one another’s subjectivity by observing the rules of civilized international relations. Those that are republics must then establish a federation. If a state is not a republic, it must become one before it can join this federation. There will be a universal, permanent peace only when all states are republics and have entered the federation. This argument seems open to the objection that a federation in which states can remain sovereign would not succeed in bringing them out of the state of nature. Either the members retain their sovereignty, in which case the state of nature continues, or they do not, in which case we have a world state, not a confederation of independent states. It is an open question whether this contradiction can be resolved (see State §3).

6 War and peace within and between communities

For Hobbes, the rule of law is possible within but not between political communities. For Kant, permanent peace based on the rule of law is possible at the international level, but it holds only among republics - that is, states governed according to the rule of law. War remains a real possibility in relations with other kinds of states. The world is bifurcated into two realms, each ruled by its own principles. The divided structure of international order implicit in these arguments appears in many other theories of international relations. Socrates suggests that Greeks and barbarians are natural enemies who may ravage one another in war in ways that are entirely inappropriate among Greeks (Plato: 469b-471c), a sentiment later echoed by J.S. Mill in the context of European imperialism. Muslims distinguish between the house of war and the house of Islam, Christian pacifists between the house of fear and the house of love. Liberal thinkers divide the world into a ‘free world’ or ‘zone of peace’ and a world inhabited by the enemies of freedom, states which, because of the character of their regimes, are not ‘peace-loving’. In the international law theory of the former Soviet Union, the rules governing cooperation within the family of communist states differ from those regulating the coexistence of communist and non-communist states.

This multilevel conception of international order continues to be influential. John Rawls’ ‘law of peoples’, for example, invokes the idea of a Kantian federation embracing liberal (what Kant calls ‘republican’) states, based on

principles of non-aggression and non-intervention. However, Rawls' law permits liberal states to intervene in the internal affairs of non-liberal societies (so-called 'outlaw states') (Rawls 1993).

Implicit in all these views are actually three rather than two levels of international order. The first is a condition of war among communities forced to take each other's power into account but unwilling to grant each other recognition. The second level is a pluralist society composed of states that recognize one another's rights as states, no matter what the character of their internal regimes; its rules are those of a minimum order of coexistence based on mutual restraint but not on shared values or a common way of life. Here, although not a constant condition, war is always possible and sometimes justified. The third level is a peaceful international society of rule-of-law states in which each conducts both its internal and external affairs according to shared standards of justice.

Watsuji Tetsurō (1890-1960)

Watsuji Tetsurō stands out as the leading thinker on ethics in twentieth century Japanese philosophy. He is regarded as a peripheral member of the 'Kyoto School' of philosophers centring around the thought of Nishida Kitarō. Like Nishida and the Kyoto School, the thought of Watsuji can be characterized by the effort to formulate a syncretic East-West philosophy developed within the framework of a Buddhist metaphysic of 'emptiness'. At the same time, Watsuji established his own highly distinctive system of ethics. He must rank as one of the most creative and profound thinkers in modern Japanese philosophy.

Watsuji was born in Himeji, Hyōgo prefecture, and entered the philosophy department at Tokyo University in 1909. From 1925 to 1934 he was a professor of ethics in the philosophy department at Kyoto University, and was a colleague of Nishida Kitarō, Tanabe Hajime, Kuki Shūzō and others associated with the 'Kyoto School' of modern Japanese philosophy (see Kyoto School). During this period Watsuji also spent two years studying abroad in Germany under the direct tutelage of Martin Heidegger. In his later years Watsuji moved to Tokyo University, where he taught from 1934 until his retirement in 1949.

The *Watsuji Tetsurō zenshū (Complete Works of Watsuji Tetsurō)* fill twenty volumes and cover a vast range of topics in philosophy, art, religion and cultural history. Whereas his earliest works focussed on Western philosophers, notably studies of Nietzsche and Kierkegaard, in his book entitled *Guzōsaikō (Revival of Idols)* (1918) he announced a 'turning point', a shift from Western individualism to a social and ethical standpoint represented by Sino-Japanese modes of thought. At this point, Watsuji's interest in Asian and Japanese moral thought was influenced especially by the *samurai* ethic of group-loyalty and self-sacrifice (see Bushi philosophy) as developed by his teacher Nitobe Inazō, in a book entitled *Bushidō, The Soul of Japan* (1905). He was also indebted to another of his teachers, the writer Natsume Sōseki, who describes the turn from egocentrism to a Buddhistic social concept of existence in his various letters, literary essays and novels. Among Watsuji's investigations into Japanese Buddhist philosophy, art and culture, of special importance is his pioneering study of Dōgen; his study *Shamon Dōgen (Dōgen, The Novice)* (1920-3) is regarded as the work responsible for rediscovering the significance of Dōgen as the foremost original thinker in classical Japanese Buddhist philosophy.

Watsuji is above all recognized for his ethics and moral philosophy, as developed in a three-volume work entitled *Rinrigaku (Ethics)*. For Watsuji a system of ethics requires an adequate definition of the person. From this perspective, he criticizes Western liberal ethics based on individualism, egocentrism and atomism as the departure point for working out a Japanese communitarian ethics of the family system based on a social, relational and contextual model of self. According to Watsuji's philosophical anthropology, the Japanese word for 'person' (ningen) clarifies the twofold structure of the self as both individual and social in character. This social understanding of the self in turn provides the basis for a communitarian system of ethics based on the 'betweenness' (*aidagara*) of persons in relation. In Watsuji's ethics, this social concept of the person as an individual-society interaction implies not only a moral but also a deeply aesthetic mode of human existence as manifest through Japanese social art forms such as the tea ceremony (*chanoyu*) and linked verse (*renga*) (see Aesthetics, Japanese).

Watsuji's social concept of Japanese personhood represents an original synthesis of Confucian and Buddhist ideals of the self (see Confucian philosophy, Japanese; Buddhist philosophy, Japanese). He articulates a Confucian model of self as a network of familial and social relationships normatively governed by rites of propriety which embodies increasingly larger social groups in the process of becoming a person. At the same time, his social concept of the person is ultimately grounded in a Buddhist metaphysic of 'emptiness' (*kū*) whereby there is a dependent co-arising of the individual and society (see Buddhist concept of emptiness). There is thus a systematic character underlying Watsuji's framework in that his aesthetics and ethics are both developed in connection to his social concept of the person, which is in turn formulated in the context of a Buddhist notion of emptiness as interrelational existence.

In his most popular book, *Fūdo (Climate)*, first published in 1934, Watsuji criticizes Heidegger's ethics as being grounded in an individualistic concept of self based on a one-sided phenomenological description of authentic human existence as a being-in-time. According to Watsuji the Japanese concept of 'person' (*ningen*) has a twofold

structure as both an individual existence in time and a social existence in a 'climate' (*fūdo*) of space. Watsuji thus establishes the basis for an environmental ethics arguing that the self arises through a relationship between the individual and its entire spatial climate including both human society and living nature (see Society, concept of).

Scathing criticisms have often been levelled against the ultra-nationalism, totalitarianism and authoritarianism of Watsuji's socio-political framework, by both Japanese and Western scholars. Critics point out that in Watsuji's ethics of the Japanese family system and its underlying metaphysic of emptiness, the result is a totalitarian ethics wherein the individual is 'emptied' into progressively larger household groups, finally emptying into the Imperial household of the Japanese nation-family through an ideal of loyal self-sacrifice to the Emperor. Although Watsuji's philosophical anthropology starts with an effort to formulate a balanced notion of self as a twofold individual-society relation, thereby to establish a middle way between individualism and collectivism, it ends by falling into a mode of totalitarian collectivism wherein the individual is emptied into the whole of the nation through the absolute negativity of Buddhist emptiness. Moreover, Watsuji's ethical framework has been charged with falling into a dangerous form of moral relativism which defines good and evil or right and wrong in terms of the particular familial group as the frame of reference, not as universal principles which transcend the group.

Weber, Max (1864-1920)

Max Weber, German economist, historian, sociologist, methodologist, and political thinker, is of philosophical significance for his attempted reconciliation of historical relativism with the possibility of a causal social science; his notion of a verstehende *(understanding) sociology; his formulation, use and epistemic account of the concept of 'ideal types'; his views on the rational irreconcilability of ultimate value choices, and particularly his formulation of the implications for ethical political action of the conflict between ethics of conviction and ethics of responsibility; and his sociological account of the causes and uniqueness of the western rationalization of life.*

These topics are closely related: Weber argued that the explanatory interests of the historian and social scientist vary historically and that the objects of their interest were constituted in terms of cultural points of view, and that consequently their categories are ultimately rooted in evaluations, and hence subjective. But he also argued that social science cannot dispense with causality, and that once the categories were chosen, judgments of causality were objective. The explanatory interests of the sociologist, as he defined sociology, were in understanding intentional action causally, but in terms of categories that were culturally significant, such as 'rational action'. Much of his influence flowed from his formulation of the cultural situation of the day, especially the idea that the fate of the time was to recognize that evaluations were inescapably subjective and that the world had no inherent 'meaning'. The existential implications of this novel situation for politics and learning were strikingly formulated by him: science could not tell us how to live; politics was as a choice between warring Gods. Weber's scholarly work and his politics served as a model for Karl Jaspers, and a subject of criticism and analysis for other philosophers, such as Karl Löwith, Max Scheler, and the Frankfurt School.

1 Life

Weber was born in Erfurt in Thuringia 12 April 1864. His father was a businessman and prominent National Liberal politician, who served in the Prussian House of Deputies (1868-97) and the German Reichstag (1872-84). The Weber household was a meeting place for prominent academics and political figures. Weber began his university training in Heidelberg in 1882 and continued it in Berlin, Strasbourg and at Göttingen to 1886. He attended lectures on law and history, passing his bar exam in 1887. He received a Berlin doctorate in 1889 for a study of medieval trading companies: his habilitation, in 1891, was for a study of legal aspects of Roman agrarian history. While preparing for his habilitation, he participated in a study under the sponsorship of the Verein für Sozialpolitik (Social Policy Association) on the subject of agricultural labourers in the East Elbian estates. He began a legal career, but soon returned to academic life. From 1894 to 1897 he was a professor of Nationalökonomie at Freiburg; from there he was appointed to a similar position at Heidelberg. A mental breakdown in 1902 led him to relinquish his teaching duties, but he soon returned to an active role as an editor and producing scholar. His sociological works began to appear after the 1904-5 publication of *The Protestant Ethic and the Spirit of Capitalism* and included a series of works on the sociology of religion dealing primarily with the theme of the economic ethics of the world religions. It is controversial whether these works or his *Wirtschaft und Gesellschaft (Economy and Society)*, posthumously published in 1922, represented the core of his thought.

His major 'methodological' essays (posthumously published as his *Gesammelte Aufsätze zur Wissenschaftslehre (Collected Essays in Scientific Theory)* in 1922) included part one of 'Roscher and Knies', published in 1903, '"Objectivity" in Social Science and Social Policy', in 1904, part two of 'Roscher and Knies' and 'Critical Studies in the Logic of the Cultural Sciences', in 1905 and 1906, and, in 1907, 'Critique of Stammler'. Among the other essays collected in the *Wissenschaftslehre* were 'The Meaning of "Ethical Neutrality"', published in 1918, which grew out of an earlier dispute with the Social Policy Association on the possibility of making policy without making value-choices that cannot be grounded scientifically, and a widely distributed speech, 'Science as a Calling', published in 1919. This and another speech, 'Politics as a Calling', given and published in 1919, were actively debated by the younger generation of intellectuals.

After the war Weber served as a member of the constitutional commission of the Weimar republic, became a professor of economics at Vienna in 1918 and Munich in 1919, and unsuccessfully pursued a career in politics. His early death came when his influence among intellectuals was at its peak. The 'Calling' speeches were an aggressive and telling formulation of a world-view that challenged the cultural and political optimism of the time,

and remained in the Weimar era as a central reference in the long-running discussion of the ‘Crisis of the Sciences’. Much of his work was published posthumously in editions that did not reflect his original intentions, but his ‘methodological’ writings were intended to be collected, and the collection largely follows his intentions. The major work published as *Economy and Society*, however, was unfinished, and his intentions for the texts that compose the extant edition were unclear.

Weber in his political writings and methodological writings rigorously separated factual and evaluative considerations, especially in connection with the consideration of policy means to political ends, in order to demonstrate the concealed and confused value premises of the teaching of the ‘Socialists of the Chair’ and the factual naïveté of ‘ethical’ political postures, and he promoted the idea that intellectual integrity demanded the making of explicit ultimate value choices. He believed that in a democratic age the only political leaders who could make free value choices and rise above mere interest-politics to greatness were those who had the charisma necessary to build a personal following, and he devoted his constitutional efforts to the task of creating means by which such leaders could rise.

2 The methodological essays of 1903-7

Weber’s major methodological article, ‘Objectivity in Social Science and Social Policy’, published in 1904, brought together the key themes of his thinking as a methodologist of social science. Weber argued that the results of the cultural sciences could be valid in an objective sense, and that indeed, ‘scientific truth is precisely what is *valid* for all who seek the *truth*’ (1904-17: 84). Yet he also argued that the objects of explanation in social science are constituted by culture-specific and discipline-specific cognitive interests and consequently are historically relative and in this sense subjective (see Explanation in history and social science; Value judgments in social science). He resolved the conflict between these two claims by a complex argument. The premises were epistemic: exhaustive description and hence explanation of concrete reality was impossible; all science is necessarily selective and concerned with a finite portion of reality. The natural sciences are, however, selective in a different way than the cultural sciences. The natural sciences select as important the segment that can be constructed as casual regularities, and take it to be the essence of reality. The cultural sciences, in contrast, begin with the finite segment that is significant to us as cultural beings with a specific culture, and then construct within this segment objects of explanation, which he called, following Heinrich Rickert, ‘historical individuals’ that are significant or meaningful to us as cultural beings. This enterprise is necessarily ‘evaluative’ in the sense that only as cultural beings do we regard these objects as significant, and culture is conditioned by valuative ideas. Accepting as our starting point this distinctive segment of reality has the effect of excluding the possibility of a social science that is based on principles like those of physics or chemistry operating at the level of an atomistic psychology, because a physics-like social science that reduced social life to elementary factors, if such a thing were indeed possible, would simply fail to apply to objects that are configured to be culturally significant to us, and would apply to a different or differently configured finite segment of reality.

One difficulty this line of argument poses arises over the question of whether causation itself is relative to our cultural starting point and interests, and is thus not a truth there for all who seek it? Weber’s response to this question is elaborated in ‘The Logic of the Cultural Sciences’ (1904-17), in which he argues that historical explanation is logically equivalent to establishing legal responsibility, and applies a contemporary legal theory of probabilistic causation, the theory of ‘objective possibility’ and ‘adequate cause’, to the problem of the objectivity of causal explanation. Legal determinations of responsibility perforce employ categories that arise from a particular and distinctive interest, the juridical interest; the cultural scientist simply has different interests and different categories.

The criteria for ‘adequate’ causation in the theory is the existence of a significant difference between the probability of a given result if a particular set of conditions held (the background probability), and the probability of the result if these conditions absent the condition in question. If purely classificatory concepts could be employed and probabilities for the two cases empirically derived, these judgments would be ‘empirical’. Thus the core of causal judgment in this theory is an objective fact. But there are two kinds of selection that are ordinarily involved in historical explanation that are not objective. Whether a difference in probabilities is significant, and hence whether a cause is ‘adequate’, depends on the set of conditions selected to provide the background probability. This choice cannot be made objectively, but must be made on the basis of the historian’s interest. A

second kind of selection occurs because 'historical individuals', the objects of the concepts of interest to historians, cannot be reduced to the sum of the ways they can be classified. So the historical analyst proceeds by constructing abstract ideal types and comparing them to other causal situations that are also known to be irreducible to the ways they can be classified. Judging the 'adequacy' of a historical causal relation is thus, in practice, largely abstract or conceptual, and unavoidably so.

Weber used these considerations to support the claim that explicitly constructed conceptual schemes were necessary in the cultural sciences, for example in economics. But he argued for a particular understanding of these constructions: as ideal types that diverged from empirical reality in its full richness. The constructed types of the cultural sciences resemble those of the natural sciences with respect to selectivity; they differ in the cognitive purposes they serve: the cultural scientist seeks conceptual clarity in relation to the particular intellectual aims of particular disciplines, each of which arises from practical purposes (see Value judgments in social science §§1-2). Weber also used this understanding of ideal-types critically, to argue against the taking of ideal type constructions for a deeper or essential reality. Crude Marxism, he thought, traded on this error, as did German theories of the state.

Weber's ideal types of legitimate rule (*Herrschaft*) were perhaps the most influential of his constructions. Weber distinguished between three kinds of belief in the legitimacy of orders or rulers: traditional, based on unwritten rules; rational-legal, based on written rules; and charismatic, where beliefs about the extraordinary character of a leader justified command. He showed how these beliefs were associated with particular kinds of social organization, and how particular kinds of belief, such as 'traditional' patrimonial beliefs were associated with orders that developed in history in particular ways. Charismatic authority, which in its pure form is personal, is unstable and short-lived, though it can be combined with other forms to ground a routinized order, such as a monarchy, which retains some charismatic elements, such as the notion of royal blood. Rational-legal orders make belief in the legality of the order the basis of legitimacy. This form characteristically results in the bureaucratization of administration. Weber explicitly intended the concept of bureaucracy to be a timeless and value free ideal type rather than a historical teleological construct. But the vision of a world of men who are little cogs trying to become bigger cogs in the huge machinery of modern bureaucracies horrified him and represented the end of the practical possibility of an individual making a choice to devote his life to some higher self-chosen goal.

3 The idea of an 'understanding' sociology

Weber's essay on 'Some Categories of Interpretive Sociology' (1913) and his introduction to *Economy and Society* stipulated a definition of sociology as the science concerned with the interpretive understanding (*Verstehen*) of social action, that is, actions that take account of others, and the causal understanding of the course and consequences of actions (see Social action). The intended meaning of an act for its agent is causally essential to an act. Accordingly, a sociological explanation of an action should be correct both on the level of cause and meaning. The understanding of meanings requires the application of type-concepts rather than empathy. Meanings are ascertained by comparing the course of action to an appropriate ideal type of a meaningful act, such as obedience to a command. Many of the causes bearing on social life, such as psychophysical or biological effects, are not intentional in character, and thus are not part of sociology as Weber defines it. 'Collective' concepts, such as the state, understood as real entities, are also excluded by Weber's definition, but the social phenomenon they refer to may be understood sociologically in terms of individual actions: the concepts are ideal-typifications of patterns of action that in turn result from the beliefs and expectations of individuals.

Subsequent commentators on Weber have made a great deal of his use of the notion of *Verstehen*, and have argued that a social science based on *Verstehen* or understanding must be radically unlike one based on any analogy to the natural sciences. The distinction between understanding and explanation was treated as a fundamental epistemological divide between two kinds of science. When Weber's works were imported to the Anglo-American world, especially during the 1930s, primarily to an audience of sociologists, this distinction was often stated as methodological distinction, and *Verstehen* was understood as a 'method'. Social phenomenologists, such as Alfred Schütz, attempted to provide a basis for an alternative social science in the problem of understanding and particularly in the problem of the attainment of 'adequacy' in the individual's understanding of another.

Weber's own statements about *Verstehen* are characteristically directed toward other issues. *Verstehen* entered

primarily in connection with concepts used by the historical figure whose actions were being explained as well as by those employed by the historical interpreter. Since the historical interpreter often was part of a culture which employed different concepts, there is a positive task of interpreting the purposes and therefore the concepts of the agent whose actions are to be explained in terms of broader and more permanent categories of action or in terms of the concepts of the historian and his own historical audience.

The treatment of intention at the beginning of *Economy and Society* distinguishes between direct and indirect evidence of intention. This is a distinction borrowed from the law, and reflects Weber's utterly unmystical attitude to assessing an agent's purposes and motives. Weber specifically rejected appeals to historical intuition. His discussion of interpretation in the beginning of *Economy and Society* treats the attribution of motivation and intent as a practical necessity dictated by the task of the inquiry, which could ordinarily be done by examining the course of action and the information available to the agent. Assessing such things requires, to some extent, thinking through a problem from the point of view of the agent, but Weber stressed that one did not need to be Caesar in order to 'understand' Caesar, but rather to assimilate the acts of a Caesar to an already 'understood' model or ideal type of action. Models of perfect rational action are, in practice, a starting point for reconstructions of intentions in complex situations, such as the battlefield decisions of a general, for which there is no alternative.

4 The conflict of values and world-view

Weber's writings on the subject of values, value-orientations, and value conflicts were directed at specific topics, such as the ethics of advocacy in the classroom, but had a well-defined philosophical core. Weber held that there were rational grounds for the selection of means to ends, and for assessing the consistency of sets of choices of ends, but that ultimate value choices could not be rationally justified. He also held that hidden conflicts became apparent when means and the subsidiary consequences of the use of the means to obtain given ends were considered, and that such conflicts were common.

In the sphere of politics, Weber argued, the decisive means is violence, and this inevitably produces conflicts of a particular kind. Consider the political leader who is an adherent to what Weber calls an 'ethic of uncompromising conviction' with respect to truth-telling in politics, that is, who upholds the value of truth-telling come what may. A foreseeable subsidiary effect of an instance of truth-telling might be to unleash uncontrollable passions. Weber argues that the only way an ethic of uncompromising conviction may be consistently upheld in the political sphere would be for its adherents to disclaim responsibility for such results of their actions, as do religious ethics which counsel their followers to 'do rightly and leave the results with God'. Weber contrasted such ethics with what he called 'ethics of responsibility', which hold their adherents to responsibility for the foreseeable consequences, both good and evil, of their actions. He rejected political moralists who obscured the tragic character of politics through wishful thinking, such as the belief that only good comes from good and only evil from evil.

Weber's characterization of the modern situation, and his explanation of it, are the subject of continuing controversies of interpretation. Weber posed the problem of explaining the distinctive 'rationality' of Western society, and particularly the dynamic process of continuing rationalization. The most famous portion of Weber's account of this process takes the form of an ideal-typical construction of the genetic development of the psychological effect of particular religious ideas. Weber argued that the Calvinist doctrine of predestination was a source of deep anxiety to believers, who sought signs that they were among the elect. He argued that the pastoral practice of responding to this anxiety through the idea that diligence in the pursuit of worldly callings and the living of a self-disciplined life were signs of election, channelled this psychological force in a direction that produced a new type of person. The presence of this new type - rationalistic, individualistic, self-examining, conscience-driven, and work-sanctifying - facilitated the process by which capitalist economic conduct and the rational organization of work displaced traditional modes of economic conduct. In the later stages of this development, however, the routines of capitalistic rationalization become inescapable, and these routines undermined religious belief. In response, religion became more 'other-worldly', and culture became the increasingly senseless pursuit of mutually antagonistic self-chosen ends in a world that had itself become 'disenchanted' or 'meaningless'.

Weber's Protestant ethic essay could be construed as an alternative to the Marxian account of the rise of capitalism. The idea that religious ideas were an extra-economic cause of economic development is in conflict with Marx's *Überbau* or superstructure theory of ideology. Weber greatly expanded on his insight that different

religious traditions create characteristically different ‘economic ethics’ or modes of thinking morally about the economic world. Most of these modes precluded the development from within the society of modern capitalism of the Western kind, which Weber took to be based on the rational organization of labour. But Weber did not address Marx’s history of capitalism directly until his late lectures on economic history, in which he provided an overall account of the history of capitalism that incorporates the few elements of Marx’s account of the development of factory production that Weber accepted. The differences in their views of this topic are characteristic: where Marx saw the organization of work into factories simply as a means of increasing exploitation, Weber argued that production was itself rationalized, and that factory work required the new type of worker that the rationalizing discipline of Protestantism was producing.

In the Weimar era, during which Marx was taken more seriously as a thinker, interpreters such as Karl Löwith, compared the two more systematically. Weber came to be regarded as the bourgeois alternative to Marx, and former members of Weber’s circle, such as Georg Lukács and Karl Jaspers, also construed Weber in this way, each for their own purposes. Jaspers made Weber into a heroic figure whose radical liberal leadership Germany had tragically failed to accept. In a work by Lukács designed to discern and root out the sources of his own ideological deviations from Communist orthodoxy, Weber was classed as a powerful exponent of irrationalism, to which dialectical materialism was the alternative. Weber later became both subject and hidden interlocutor for the critical theorists of the Frankfurt School, and as they and their successors became concerned with the problem of modernity, Weber came to be regarded as a major theorist of modernity (see Frankfurt School).

Weil, Simone (1909-43)

Simone Weil's life and work represent an unusual mixture of political activism, religious mysticism and intense speculative work on a wide range of topics, including epistemology, ethics and social theory. Much of her most important writing survives in fragmentary form, in notebooks published after her untimely death. Though Jewish by family, her attitude to Judaism was largely hostile; and despite a deep commitment in the later part of her life to Christian ideas and symbols, she consistently refused to be baptized. Her religious views are eclectic in many ways, drawing on Plato and on Hindu sources. In everything she wrote, she was preoccupied with the dehumanizing effects of economic unfreedom and the servile labour required by industrial capitalism; but this is only one instance, for her, of the experience of 'necessity' or 'gravity' that dominates material transactions. The essence of moral and spiritual action is the complete renunciation of any privileged position for an ego outside the world of 'necessity'. Such renunciation is the only escape from necessity, in fact: what she calls 'decreation' becomes our supremely creative act, since only in the ego's absence is love, or an apprehension of non-self-oriented goods, possible. Marx, Kant and the gospels are all in evidence here.

1 Being in the world

Born in Paris in 1909, Weil studied at the Lycée Henri IV and the École Normale Supérieure. Her career as a schoolteacher was interrupted by a year of manual work in a factory and a brief and disastrous spell as a volunteer in the Spanish Civil War. Ill-health obliged her to resign from full-time work, and, after living with her parents for a time (and working on the land in Southern France after the German occupation), she joined them in emigrating to New York in 1942. By the end of that year, however, she was in London, working for the Free French. Overwork, a lung infection and the refusal to eat more than the current level of rationing in France led to a collapse in the spring of 1943. In hospital, she refused food and resisted medical help, and, because of this, her death in August 1943 was recorded as suicide. Some of the most significant of her notebooks are from the period in the South of France (1940-2) and the months in New York and London: they show very clearly the effects upon her thinking of a profound experience of religious conversion in 1938, but continue to develop themes that she had begun to explore almost a decade earlier.

Her earliest published work, from her time at the École Normale, was much influenced by her lycée teacher Alain (Émile Chartier), an eccentric and charismatic thinker who stressed the radical freedom of the will and the intimate connection of will and intelligence: mental action is an indivisible whole, a moral self-location in response to the experience of the body's life in the world. Weil's early work applies this perspective to the question of labour: work is the antithesis to the immediacy of thought, because it demands that we engage in actions we do not want to perform in order to realize the goal we *do* want. Such actions have no intrinsic relation to the mind's movement towards its goal; but the pure freedom of thought and will has to be activated in the concrete world by mediation and indirectness. Work is thus a paradigm of all she would later designate as necessity - that which imposes itself on mind. Yet without the primitive mental act meeting frustration in this way, there would be no *conceptuality* of the world as extended in time and space, no way of talking about objects or about duration (what intervenes between desire and realization).

We form concepts as we form 'strategies' for getting what we want. Our concepts are neither Platonic givens nor abstractions from sensation, but more like compact sets of instructions for negotiating obstacles. They are - as Weil's early *Lectures on Philosophy* put it - the product of 'a sort of dance', the body learning its way around in a world where realization is *not* contemporary with desire. And what we call 'reality' is thus neither purely given nor self-constructed but, as she says in a late fragment, 'a certain relationship to what is given'. This relationship is charged with ambiguity. At the simplest level, the body learns to interpret situations in a way that is more or less instantaneous: it 'reads' what has to be done (as promptly as we interpret marks on paper as words). But reading becomes more complex as we reflect on it, and the imagination intrudes - a faculty which for Weil is always morally shady. Imagination pulls apart the direct relationship of embodied thought to the surrounding obstacles, denying the character of these obstacles, seeking to avoid the suffering of real work, offering *ersatz* gratifications for our desires. This is specially acute in our relations to other subjects: slavery is the imposition of my (imaginative) reading of another person upon their reality (their actual relation to me). So being in the world as a moral subject, wanting the truth, wanting to live in appropriate relation to the given, requires a fierce assault on the

imagination, so that we may be returned to a direct confrontation with necessity.

2 Decreation and grace

There are two implications to this programme. First, all our *specific* goals or desires are likely to be flawed, because they invite us to form images of what we want, and so to evade necessity. Second, the root of corruption in our seeing and acting is the desire not to lose control, the longing to pretend that the immediacy of thought can be translated into our negotiations with what is given. The moral and spiritual task is to purify our desire by the rigorous renunciation of the ego, its position, its ‘rights’, its account of its individual wants. Pure desire is absolute consent to what is given, a submission to the otherness of the world that abandons any claim to a place, over against the world, from which I can manipulate the given. In the most radical expressions of this in the late notebooks, Weil will speak of the need for the ‘I’ to disappear: ‘To say "I" is to lie’, to defend an illusory self against necessity. The residual Cartesian and Kantian elements in her earlier thought are here subjected to their most ruthless purgation - though not without leaving strong traces. Here too her religious vision comes most clearly in view. The total acceptance of the given, the ‘desire’ for reality, *is* the desire for God, the only proper object of desire, since God is no particular thing. The Christian narrative shows us a God who wills the universe into being, a universe that is devoid of God, in the sense that God is not identical with any object or state of affairs in it. Thus God’s supreme liberty is expressed in creation as consent to an order of God-less necessity. Creation is divine renunciation; and the further narrative of the incarnation shows God becoming present in the Godless world in the only way possible - as a person without power or rights, becoming finally a dead body on the cross and a passive, mute object in the bread of the Mass. The Christian God is thus absent from the world but also, consequently, ‘present’ in the very character of the world as God-forsaken.

To accept the world is to love God. But the introduction of God into the discourse here has its paradoxical side. While we can deploy the theological narrative of creation and incarnation, we have no possibility of constructing a religious metaphysic in the usual sense. As soon as we conceptualize and represent God and an existing reality over against us, we lose sight of the ‘real’ God; and, on the basis of what is said elsewhere about reality, we should conclude that the reality of God is a particular relation between the self and what is given *in its entirety*. Weil’s kinship is with the tradition, inside and outside Christianity, of regarding with suspicion any suggestion that God is a kind of object among other possible objects of experience. She is not straightforwardly aligned with those radical theologians who deny the extra-mental reality of God.

When the ego is displaced in this complete acceptance, what follows is ‘grace’ or ‘the supernatural’, a relation to persons and things devoid of private interest and desire. Only this can properly be called love. The connection between such love and any particular person or object is complex, and Weil’s interpreters are not at one in analysing it. On the one hand, the sheer otherness of the world in its concrete variety is precisely what resists and checks my ego; and I begin to learn something of grace by submission to this concrete otherness, by what Weil calls ‘attention’. One of her most deservedly famous essays (‘Reflections on the Right Use of School Studies with a View to the Love of God’, written in 1942 and published in *Attente de Dieu* (1950a)) elaborates the spiritual significance of intellectual discipline. But, on the other hand, love is not properly bestowed on any individual object in its historicity, because this would be to make it serve transient needs or projections of the ego. Only what is timeless can be loved without corruption. There is no easy resolution of this tension, which points up central difficulties in Weil’s conception of the self: the self’s material and historical identity is both axiomatic and the source of ‘infinite error’.

3 Violence and justice

This creates some problems in her social thinking. Much of what she writes suggests that social life and cooperative labour is always ‘primitively’ a common sacrifice of individual desires before the given imperatives of collaboration. The struggle for social dominance is the struggle for the position of least sacrifice. She writes with great eloquence about the distortions of awareness produced by the exercise of force, both in the powerful and the powerless, and she is deeply sceptical about prevailing models of political legitimacy, resting as they do upon uneasy truces between different centres of power and interest. In her very substantial late (and unfinished) essay *L’enracinement* (1949) (*The Need for Roots* (1952)), designed in part as a vision for post-war France, she pleads for a society in which the impersonal instrumentalism of labour in a capitalist economy is replaced by work that can more readily be grasped as direct confrontation with necessity. This implies a radical dismantling of

international capitalist structures, including colonialism, and a reorientation towards local (regional rather than national) sociopolitical units. It also means the dismantling of 'modern' political structures, such as political parties and trade unions, since these take for granted the 'violence' of competitive interests. Justice will emerge not from bargaining but from the common reality of encounter with necessity; and this spiritual anchor for justice will be nourished by the corporate appropriation of a local past, a specific and harmonious culture. Weil did not shrink from the further implication that there could be no long-term future in such a society for religious or cultural minorities: they would be gently but firmly educated out of existence. Nothing could more clearly underline her own passionate rejection of her Jewishness, her own 'roots'. It is a final, and revealing, paradox in an *oeuvre* full of contradictions, yet so often profound in its critiques of modernity, of moral illusion and of cheap religious consolation. Only gradually has she come to attract serious philosophical study, rather than either mere abuse or hagiography; but she deserves just the unsparing 'attention' she herself so forcefully commends.

ROWAN WILLIAMS

List of works

Weil, S. (1988-) *Oeuvres complètes*, Paris: Gallimard.(The collected works.)

Weil, S. (1947) *La Pesanteur et la grace*, Paris: Plon; trans. E. Crauford, *Gravity and Grace*, London: Routledge, 1952.(Selected aphorisms from the *Cahiers*, often, regrettably, quoted or discussed without reference to their context in these notebooks.)

Weil, S. (1949) *L'enracinement*, Paris: Gallimard; trans. A. Wills with a preface by T.S. Eliot, *The Need for Roots*, London: Routledge, 1952.(Written in 1943, shortly before her death, this was intended both as an examination of the causes of alienation (especially among workers) in modern society and also as a blueprint for a post-war future in which individuals might enjoy a fruitful, rooted relation with society as a whole.)

Weil, S. (1950a) *Attente de Dieu*, Paris: La Colombe; trans. E. Crauford, *Waiting on God*, London: Routledge, 1951.(A collection of essays and meditations, largely but not exclusively religious. It has been the most widely read introduction to Weil's thought.)

Weil, S. (1950b) *La Connaissance surnaturelle*, Paris: Gallimard.(Contains Weil's *Notebooks* written in New York in 1942.)

Weil, S. (1951a) *La Condition Ouvrière*, Paris: Gallimard.(A painstaking diary of the time she spent labouring in factories (Alsthom and Renault) in 1934-5, with a series of texts reflecting on the experience in political and moral terms.)

Weil, S. (1951b) *Intuitions pré-chrétiennes*, Paris: La Colombe.(Material in Greek philosophy and its relation to Christianity.)

Weil, S. (1951c) *Lettre à un religieux*, Paris: Gallimard; trans. A. Wills, *Letter to a Priest*, London: Routledge, 1953.(A long letter addressed to a Dominican, le Pére Couturier, outlining her doubts about, and spiritual affinities with, Catholicism. Written in the autumn of 1942, ten months before her death.)

Weil, S. (1951d) *Cahiers*, Paris: Plon; trans. A. Wills, *The Notebooks of Simone Weil*, London: Routledge, 1956; also trans. R. Rees, *First and Last Notebooks*, London: Oxford University Press, 1970.(Fundamental for her developed religious metaphysics, though often very difficult for the interpreter.)

Weil, S. (1953) *La source grecque*, Paris: Gallimard.(Essays on Greek literature, also on Plato.)

Weil, S. (1955) *Oppression et liberté*, Paris: Gallimard; trans. A. Wills and J. Petrie, *Oppression and Liberty*, London: Routledge, 1958.(Contains the essay 'Reflections Concerning the Causes of Liberty and Social Oppression'. This considers the manner in which our social development has put limitations upon, rather than enhancing, human liberty.)

Weil, S. (1957) *Intimations of Christianity among the Ancient Greeks*, chapters from 1951b and 1953, trans. E. Geissbuhler, London: Routledge.(Finished reviews, and the texts of talks given in the Dominican Monastery at Marseilles. Discusses Greek philosophy as a harbinger of the Christian message.)

Weil, S. (1959) *Leçons de philosophie, Roanne 1933-4*, Paris: Plon; trans. H. Price with an introduction by R. Rees, *Lectures on Philosophy*, Cambridge: Cambridge University Press, 1978.(Provides insights into her earliest philosophical positions.)

Weil, S. (1962) *Selected Essays: 1934-1943*, trans. R. Rees, Oxford: Clarendon Press.(Mostly political essays.)

Weil, S. (1966) *Sur la Science*, Paris: Gallimard.(Early work on Descartes, and later essays on science.)

Weil, S. (1970) *Science, Necessity, and the Love of God*, trans. R. Rees, London: Oxford University Press.(Essays on science and on Plato, from the 1953 work.)

Winch, P. (1989) *Simone Weil: 'The Just Balance'*, Cambridge: Cambridge University Press.(Incomparably the best philosophical study, drawing out parallels with Wittgenstein.)

Weinberger, Ota (1919-)

Weinberger is noted as a proponent of 'institutionalist positivism' in legal theory. By contrast with earlier forms of so-called 'institutionalism' in law, Weinberger advances a theory in which norms are ideal entities linked by logical relations inter se*, while being at the same time social realities identifiable in terms of the effect they exercise in guiding human social behaviour. The institutions which make possible this duality of ideal entity and social reality have themselves to be understood as structured by norms. Hence, in contrast with earlier proponents of institutionalism, who denied the foundation of law in norms, Weinberger is normativist in his approach; and for the metaphysical vitalism of precursors, he substitutes a social realism.*

Born in Brno, Czechoslovakia, Weinberger trained in law and philosophy in Brno under František Weyr in the 'Brno School' of the 'Pure Theory of Law' (see Kelsen, H.), developing an early interest in the logic of norms. Imprisoned in a wartime concentration camp, he was able to resume his career as a scholar after 1945 in the difficult circumstances of post-war Czechoslovakia. During the 'Prague Spring' of 1968, he was able to leave for Austria, where he became Professor in Philosophy of Law in Graz, continuing actively as professor emeritus after retirement in 1988.

While rejecting ethical cognitivism, and with it natural law, Weinberger sees his position as promising some *rapprochement* between positivism and natural law theory (see Legal positivism §5; Natural law §1). For he acknowledges that concerns with justice are inherent in attitudes to law. He also fully acknowledges a place for reason - for rational analysis - in practical matters, but denies that reason ever finally determines the right, this being dependent on a taking-up of practical attitudes in a non-rational or pre-rational way. Reason and justice have a critical role to play in reflection upon action. But justice is never itself a primary motive to action; rather, it sets critical constraints on conduct whose motivation is fundamentally utilitarian (see Justice, equity and law).

Weinberger's early work was in spheres of logic which eluded even a stringent communist censorship, and already in his pre-Graz period he made significant contributions to the study of norm-logic, a field still in its infancy. He sees two spheres for this, one concerning the logical relations of established norms, the other concerning their establishment, in particular the question what logical account can be given of the way in which a power-exercising act under a norm of competence is to be understood as validly establishing a lower-order norm (see Norms, legal). In parallel to his differentiation of justice and utility, he has distinguished the logic of action from norm-logic, producing what he calls a 'formal-finalistic' or 'formal-teleological' theory of action, in which action is seen as activity guided by a processing of information. In this context, he insists upon the ultimate non-derivability of practical from theoretical information. This is his version of the non-derivability of 'ought' from 'is'. He rejects John Searle's purported derivation, reflection on which contributed greatly to development of his own conception of institutions such as promising or law-making.

Koller, P. *et al.* (1994) *Institution und Recht: Grazer Internationales Symposion zu Ehren von Ota Weinberger (Institution and Law: an International Symposium at Graz in Honour of Ota Weinberger)*, Berlin: Duncker und Humblot.(This volume, which appears as Beiheft 14 of the journal *Rechtstheorie*, contains a series of tributes to and arguments with Ota Weinberger by a significant group of colleagues and friendly critics; it also contains a complete bibliography of Weinberger's vast output of writings in languages other than in English, and of the

smaller body of his work, including journal articles, published in English.)

Welfare

Notions of welfare occur widely in political philosophy and political argument. For example, utilitarianism is a social ethic that may be interpreted as giving a pre-eminent place to the idea that the welfare of society should be the overriding goal of public policy. Discussion of the ethics of redistribution focuses upon the institutions and practices of the so-called welfare state. Even those not convinced that we can validly speak of animal rights will often accept that considerations of animal welfare should play a part in legislation and morals. Moreover, the concept of welfare is clearly related to, and indeed overlaps with, concepts like 'needs' or 'interests', which are also central to public decision making and action.

Welfare can be thought of in three ways. Firstly, there is a subjective sense, in which to say that something contributes to a person's welfare is to say that it makes for the satisfaction of a preference. However, people can adapt their preferences to their circumstances, and happy slaves might be better off changing their preferences than having them satisfied. This thought leads on to the second sense of welfare as doing well according to some objective measure, like the possession of property. However, this conception can ignore subjective differences between people and fail to account for their capacity to take advantage of their objective circumstances. Hence, a third conception of welfare would make the capacity to take advantage of one's possessions an essential element of welfare. A satisfactory overall conception will have to bring these ideas together.

1 Welfare as preference

A common, perhaps the predominant modern, approach to the idea of welfare is to see it as the satisfaction of individual preferences or wants. This idea derives from the Benthamite felicific calculus (Bentham 1789) as mediated through modern welfare economics and the idea of consumers' utility. In this conception, persons are regarded as having preferences over various commodities (apples versus oranges) or states of the world (a world with or without the whale), and peoples' welfare, or utility, depends upon the extent to which their most highly ranked preferences are satisfied.

The notion of preference in this conception hangs uneasily between the notion of wanting and that of choice. Preferring commodity A to commodity B can seem to be like wanting or desiring to possess A rather than B, where the want is either a mental event or a disposition. On the other hand, some accounts of preference identify the notion simply with choice, asserting that all that is involved in preferring commodity A to commodity B is that one would choose to have A rather than B, without any assumptions being made that a choice reflected any inner feelings.

Whichever of these two views of preference is chosen, the main thrust of the preference-based conception of welfare is that the welfare of a person is to be judged from their point of view. This conception is particularly suited to those political theories that stress the diversity of individuals and societies, thereby implying that it is impossible to construct generalizations of what makes life go well for people.

Despite its appeal, the preference-based conception of welfare has difficulties. Some have urged that there must be limits on the desires or wants that we can sensibly ascribe to individuals, so that we should simply find unintelligible, not just unusual, someone who said that they wanted, say, a saucer of mud, without specifying any recognizable purpose for it. From this point of view the subjectivism implicit in the preference-based conception of welfare would be bounded by an understanding of desires that it would be intelligible to ascribe to individuals.

However, even within these limits, there are problems with treating welfare as preference. Slaves and harassed tenants may find that they adapt their preferences to their lot, coming to believe that it is in the nature of things. But if, after a while, such persons find that they prefer secure bondage to previously yearned for freedom, has their welfare increased? In terms of the preference-based account it has, but to many this has seemed counterintuitive. Limiting one's wants in this way seems instead to be the model of a frustrated life.

For these sorts of reasons theorists who favour a preference approach have sought to modify its simple form to take into account not raw preferences but informed ones. If the previously resigned come to see that things could be other than they are, then their preferences may change. Taken to the limit, the thought is that it is only the preferences that persons have in the full knowledge of their circumstances and the possibilities open to them that

could form the basis for a judgement about their welfare. If I know all there is to know about a commodity or a state of the world and I still choose it in preference to something else, then we might want to say that I have thereby established what makes for my welfare.

One advantage of this approach is that it seems to offer a coherent analysis of the idea of human dignity. For example, when J.S. Mill (§9) argues that it is better to be Socrates dissatisfied than a fool satisfied, because the fool knows only one side of the story but the dissatisfied knows both, he is implicitly appealing to a hypothetical choice or preference criterion, in order to make the idea of welfare consistent with some idea of human dignity.

Despite the appeal of the account, it raises a number of questions. To say that someone currently prefers A to B, in their present state of knowledge, but would prefer B to A if they were fully informed invites the question of how we might know what the hypothetical preference was. In the absence of any theory about how people choose, it is impossible to say. Moreover, if there were such a theory and if it were based on accounts of how in fact the bulk of persons do choose, it looks as though the account is merely slipping into an objectivist account of welfare reflecting views about human nature and what makes things go well for people in general (see Needs and interests).

A final difficulty with the preference-based account, in either its raw or informed preference view, is the difficulty of making interpersonal comparisons of welfare. The problem here is that interpersonal comparisons seem plausible (we think we know that the prince is better off than the pauper), but it is difficult to see how such judgements could be intellectually justified (see Economics and ethics; Utilitarianism).

Within the preference-based account these difficulties appear to be insurmountable. If the welfare of persons is simply constituted by their preferences over alternatives, what evidence could be employed to make comparisons? Ingenious attempts have been made to employ the idea of extended sympathy in this context, in which a judgement of interpersonal comparisons is made by someone saying that they would rather be person A, with all that A has, than person B, with all that B has, but it has been pointed out that this merely shows that people think they can say what they find attractive or otherwise in the position of others, not what is comparatively of value in the position of others.

2 Objective accounts of welfare

Objective accounts of welfare appeal to the thought that there are features of the circumstances, position or characteristics of persons that enable us to judge how well off they are.

There are in principle two forms of objective account of welfare; the criterial and the indexical. Criterial accounts state that welfare is made up of those things that are necessary to achieve some end state or goal, such as human flourishing or agency. To enjoy a certain level of welfare, on such accounts, is simply to be in possession of just those goods that make the achievement of the goal or end state possible. Special mention should be made in this context of Rawls' notion of 'primary goods' (Rawls 1971) (see Rawls, J. §1). These are defined as those things it would be rational to want if one were to want anything at all. Although this seems like a subjectivist notion, it is more plausibly construed as objectivist, since the wanting is grounded in external reasons, and the criterion is normally interpreted by appeal to standard empirical evidence about what is necessary to lead a life in society.

Indexical accounts simply list goods thought to be components of welfare, such as health, possessions and good fortune. In practice these two distinct logical conceptions, the criterial and the indexical, turn out to have similar implications, since the criterion of welfare will typically end in a list of some sort. Thus, Rawls' primary goods are listed as income and wealth, opportunities and powers and the bases of self-respect, and subsequent commentators (for example, Pogge (1989)) simply cash them out as familiar lists of rights.

One appeal of the objective approach is that it seems consistent with much that is ordinarily said and thought about welfare. It seems to make sense to say that we are well off when our health is good, our careers go well, our possessions and prospects are secure, our political and civil rights protected and our personal relationships flourishing. Moreover, such an objective approach would solve the problems associated with the interpersonal comparison of welfare. Although it might be difficult to combine the various dimensions of wellbeing into a single index, we could at least measure how well things were going for people by reference to such criteria as have been listed. Indeed, there is a branch of social science - the construction of social indicators - that is devoted to

measuring the welfare of people in society by reference to such criteria.

At this point the subjectivist will object and say that just as possessions do not make for happiness, so doing well on some objective list does not make for welfare. There are a number of reasons why this might be so. Certain spiritual aspirations may mean that people have to forgo their possessions in order to discover their soul, and Brentano is said to have treated the blindness of his old age as a blessing because it meant that he concentrated on his philosophy. Moreover, how in the absence of an appeal to subjective assessment do we evaluate conflicts among goods on the list? For example, certain risky occupations involve a trade-off between income and the chance of accidents leading to ill health. How people balance the conflict between income and additional health risks seems properly a matter for their own judgement, for which the most obvious rationalization is the thought that the assessment of welfare must be done from the point of view of the person experiencing it.

Yet these anti-objectivist arguments are not without problems. Cases of giving up one's possessions to save one's soul or the example of Brentano's blindness, although revealing, may be treated as special in the sense that they give extended meaning to a concept but do not affect its central application. The argument from the trade-off of benefits may be reinterpreted to yield objectivist conclusions, if we admit that it makes sense to have an external evaluation of the choices that people make. It seems entirely plausible to think that we can know in some cases that people make the wrong choice, from the point of view of their own welfare, between income and health, and we may also be critical of social arrangements that give the poor hard choices between earning a living and avoiding an unsafe working environment. All such judgements presuppose a certain objective conception of welfare.

The appeal to diversity does have a point, however. Suppose we observe a community of persons with roughly similar material circumstances and similar educational opportunities pursuing different occupations, different lifestyles and taking different attitudes to risk. Each person may enjoy quite distinct bundles of possessions and characteristics. Yet we may judge the members of the community to have similar levels of welfare, in the sense that each person has used similar resources to different effect according to their own conception of what is good for them. This line of argument might suggest that we can reconcile objective and subjective accounts of welfare provided we take into account the ability of people to use the resources at their disposal. This thought brings us to the third conception of welfare, namely that of welfare as capabilities.

3 Welfare as capabilities

Amartya Sen has argued that to treat welfare simply as a function of the commodities that people have is misleading, since it ignores the capacity or capability that people have to use those commodities to their own advantage (Nussbaum and Sen 1993). An obvious example would be the contrast between the physically handicapped and the able-bodied. The former may need more resources to bring them up to the same standard of living as the latter. The implication of this view is that we need to take into account the ability of people to use their objectively given level of resources to achieve welfare in their own terms.

Sen suggests that we need to base our conception of welfare on capabilities, rather than commodities, in order to do justice to this insight. However, it is doubtful if this implication can be drawn. Capabilities are difficult to measure directly, and the way in which the idea has in practice been developed is in terms of social indicators of the rather conventional objectivist sort. However, the value of the idea of capabilities is that we need to take into account this dimension of welfare if we are to make adequate interpersonal comparisons.

4 Conclusion

Can we extract a coherent conception of welfare from these competing views? If we accept that human diversity means that people will find their welfare in diverse combinations of goods, then there has to be an irreducibly subjective element to our concept of welfare. One way to avoid the problems with such an account is to modify our assessment of peoples' choices and preferences not in terms of a hypothetical choice that they would make, but in terms of our knowledge of preferences generally exhibited by persons in circumstances we understand. Moreover, we should further modify this assessment by a calculation of how far people are able to take advantage of the resources at their disposal, which is in large part an empirical matter.

If we take the notion of welfare to have both these subjective and these objective elements, allowing the subjective to operate within the limits of our understanding of what in general makes life go well for people, then we are

faced with the problem of how broadly we are to construe the notion of welfare. In particular, is individual freedom or autonomy a component of welfare or a distinct characteristic of humans? There is probably only a conventional, rather than essentialist, answer to this question, but if it is sensible to ask how valuable it is for people to secure their autonomy, then it would seem to be more plausible to make freedom an element of welfare rather than distinct from it. As such, the concept of welfare will always remain central to questions of political philosophy.

Weyl, Hermann (1885-1955)

A leading mathematician of the twentieth century, Weyl made fundamental contributions to theoretical physics, to philosophy of mathematics, and to philosophy of science. Weyl wrote authoritative works on the theory of relativity and quantum mechanics, as well as a classic philosophical examination of mathematics and science. He was briefly a follower of Brouwer's intuitionism in philosophy of mathematics. Upon moving closer to Hilbert's finitism, he articulated a conception of mathematics and physics as related species of 'symbolic construction'.

Hermann Weyl was born on 9 November, 1885 in Elmshorn, near Hamburg, Germany. He received his doctorate in mathematics under the direction of David Hilbert at Göttingen University in 1908. From 1913 until 1930, when he returned to Göttingen as Hilbert's successor, Weyl was Professor of mathematics at the Federal Institute of Technology in Zurich. As head of the world-renowned Mathematical Institute in Göttingen when the Nazi regime came to power in 1933, Weyl's unsuccessful attempts to protect his colleagues from arbitrary dismissal prompted him to accept, later that year and at Einstein's urging, an appointment as Professor at the newly formed Institute for Advanced Study in Princeton. The recipient of many prizes and awards for his mathematical work, including the Lobachevskii prize in 1925 for his geometrical research, Weyl was elected a contributing member of the Royal Society of London in 1936. Upon his retirement from the Institute in 1951, Weyl divided his time between Princeton and Zurich where he died of a heart attack on 9 December 1955.

A mathematician of extraordinary depth and breadth, Weyl worked in nearly all parts of mathematics: analysis, geometry, number theory, algebra and mathematical logic. He also continued the Göttingen tradition of Felix Klein and David Hilbert of carrying out mathematical investigations of fundamental questions in theoretical physics. In the decade 1917-27 he was at the height of his powers, producing a succession of contributions of the highest order to mathematics and to physics. In 1918 he published *Raum-Zeit-Materie*, the first self-contained treatment of Einstein's new general theory of relativity, which Einstein termed 'a masterful symphony'. Running through five editions by 1923, the work was no mere exposition but considerably illuminated the mathematical and philosophical foundations of the theory. For example, Weyl was first to show that there is a natural geometric but non-metrical expression ('manifold with an affine connection') for the combined gravitational-inertial field, underscoring that in general relativity gravitation is but counterpart to inertia.

Still in 1918, Weyl proposed a generalization of the Riemannian geometry underlying the Einstein theory which contained an additional metrical term formally analogous to the tensor expression for the electromagnetic field. As gravitation and electromagnetism were then the only known physical forces, Weyl's geometry appeared to account for all known physical phenomena in terms of the metric of spacetime. Though his theory did not survive the advent of quantum mechanics in 1925-6, Weyl's approach considerably influenced Einstein's first attempts at a unified field theory, and its central principle, 'local gauge [scale] invariance', now reinterpreted in the context of quantum theory, remains a leading principle of the physics of elementary particles. As an outcome of his research on group representations in 1925-6, which Weyl himself viewed as his greatest mathematical achievement, he pioneered investigation of the connections between group theory and the new quantum mechanics in 1927.

Despite his then deep involvement with the theory of relativity, Weyl also published in 1918 *Das Kontinuum*, a controversial monograph on the foundations of analysis. In agreement with the diagnosis of Poincaré and Russell that the root of the crisis in the foundations of mathematics concerned the freedom in unrestricted set theory to form 'impredicative' sets or classes, Weyl sketched out an iterative method of set formation (essentially a predicative set theory) in whose terms some, but not all, of classical analysis might be reconstructed. The remainder, Weyl proclaimed, would simply have to be jettisoned as illicit extensions of mathematical thinking. Thus would be surrendered such a fundamental theorem as that every bounded set of real numbers contains a unique least upper bound. At the time predisposed toward Husserlian phenomenology, by 1920 Weyl had abandoned his own attempts to resolve the crisis in foundations and joined the Dutch mathematician Brouwer in intuitionism. Weyl proved to be a wayward disciple. While endorsing the conception of the continuum as an *open* and not a *completed* totality, Weyl differed fundamentally from Brouwer in linking the grounding of analysis (for example, the concepts of real number and function) with its applications, especially in physics.

In the late 1920s, Weyl argued that the interconnected character of justification of individual mathematical

assertions, as shown in Hilbert's finitism and paralleling the epistemological situation in physics where theories as a whole confront the evidence of experience, posed 'a decisive defeat for the program of pure phenomenology' in the foundations of mathematics. In later writings, Weyl emphasized the *essentially* symbolic character of mathematics and physics. As species of 'constructive cognition', both exhibit the freedom of mental operations to idealize from the given and to introduce symbols, which may then be freely manipulated according to certain rules. In this way symbols acquire a relative independence. Agreeing with idealism that scientific objectivity is not given but is constructed in symbols, Weyl nonetheless posited an unbridgeable chasm between the objective world of symbols and the ego, the 'light of consciousness'.

Weyr, František (1879-1951)

František (Franz) Weyr was Professor in Legal Philosophy and Public Law in Brno, Czechoslovakia, and a main author of the Czechoslovakian Constitution of 1920. His influence on Czechoslovakian jurisprudence was exceptional. He advocated the 'Pure Theory of Law', demanding that law be studied in a methodologically distinct way, pure of natural-scientific or ideological inputs. He was founder and leader of the 'Brno School' of Pure Theory (or 'Normative Theory', in his preferred terminology). This school stands close to the Vienna School of Hans Kelsen.

Weyr and Kelsen were also close in political stance. Both fought for democracy and against the Austrian monarchy, with its elements of a police state. Weyr's analysis of the relation between private and public law is particularly pro-democratic in tendency; according to him, procedures in public law no less than in private law are themselves bound by law.

In Weyr's conception, law belongs to a legal order which is: (1) a logically unitary system of norms ascribed to the state; (2) a dynamic system with hierarchical structure; (3) valid under a presupposed basic norm; (4) subject to cognition of its content understood as *sui generis* and studied in abstraction from social and evaluative considerations (thus jurisprudence as cognition differs from legal politics as volition); (5) identifiable through attribution to the state as their ideal subject. (Hence Weyr sharply rejects Kelsen's sanction theory of legal norms; Norms, legal §2.)

Weyr's philosophical background is Kantian, grounded in the opposition of 'is' and 'ought', cognition and volition. Thus his theory of law and of legal processes explains cognition of them in terms of their formal and general validity. He accepts Kant's theory of the nature of cognition so far as it stresses the distinction of 'is' and 'ought', but rejects Kant's commitment to a form of natural law theory (see Legal idealism §2; Natural law). The dualism of 'is' and 'ought' is not only semantic, but rooted in different rational relations in the respective fields. Weyr is a strict positivist and value-relativist, and founded legal methodology on the difference of argumentations about the existence of law and about its merit as such. The realm of jurisprudence is a realm clearly distinct from that of nature: in law (and morality) free action is essential, whereas nature is governed by causality. Latterly, he tended towards Karel Engliš' triadic view of the forms in which we apprehend reality, namely causality, teleology and normativity, but underlined the nearer relation between teleology and normativity. He articulated explicitly the problem of the specificity of norm-logical relations, and acknowledged that the logic of descriptive language is inapplicable to norms. He rejected the norm-logical scepticism of Engliš and Kelsen.

Elements of Weyr's theory that remain of importance are: the view that structure-theory is the basis of legal theory, and that it should be linked with an appropriate theory of legal argumentation; and the dynamic theory of law as foundational for investigations of legal processes and legality. Weyr's and Kelsen's teachings belong to the first phase of analytical jurisprudence, seeking a universal structure of all law. The present second phase looks for differentiations of legal structures, thus transcending the Brno and Vienna schools alike. The postulate of strict purity of jurisprudence should be given up; what survives is Weyr's postulate that methods of inquiry must not be mixed up, but must match objects of inquiry.

Whewell, William (1794-1886)

William Whewell's two seminal works, History of the Inductive Science, from the Earliest to the Present Time (1837) and The Philosophy of the Inductive Sciences, Founded upon their History (1840), began a new era in the philosophy of science. Equally critical of the British 'sensationalist' school, which founded all knowledge on experience, and the German Idealists, who based science on a priori ideas, Whewell undertook to survey the history of all known sciences in search of a better explanation of scientific discovery. His conclusions were as bold as his undertaking. All real knowledge, he argued, is 'antithetical', requiring mutually irreducible, ever-present, and yet inseparable empirical and conceptual components. Scientific progress is achieved not by induction, or reading-out theories from previously collected data, but by the imaginative 'superinduction' of novel hypotheses upon known but seemingly unrelated facts. He thus broke radically with traditional inductivism - and for nearly a century was all but ignored. In the Philosophy the antithetical structure of scientific theories and the hypothetico-deductive account of scientific discovery form the basis for novel analyses of scientific and mathematical truth and scientific methodology, critiques of rival philosophies of science, and an account of the emergence and refinement of scientific ideas.

1 Life and works

Whewell was born on 25 May 1794, son of a master carpenter in Lancaster. He died on 6 March 1866, Master of Trinity College, Cambridge, and one of the most eminent and prolific individuals of the era. His works include scientific research, physics and mathematics textbooks, books on ethics and law, university education, natural theology, church architecture, scientific nomenclature, political economy and the history and philosophy of science. He wrote poetry, translated Greek and German classics and edited the works of Hugo Grotius and Isaac Barrow. He was an active member of more than a dozen learned societies, a force in the founding and running of the British Association for the Advancement of Science, an influential Master of Trinity (1841-66), and dominant Vice Chancellor of Cambridge University during two terms of office (1842 and 1856). Whewell, however, was not just a polymath. He wrote with the explicit view not merely of encompassing the world of early Victorian learning, but of synthesizing it and rendering it a unified intellectual whole.

Drawing on the *History* that endeavoured, for the first time ever, to chart the development of all known 'inductive sciences', the *Philosophy* proposes a novel theory and methodology of science that describe the nature, structure and aims of a well-formed natural science, explain how scientific discoveries are made and propose ways of retrospectively assessing their truth. The *Philosophy*, however, deviated too sharply from the prevailing empiricism, advocated, for example, by John Herschel and John Stuart Mill, to obtain acceptance in its time (see Mill, J.S. §5; Empiricism; Inductive inference §4). Only recently, especially in the light of Karl Popper's critique of inductivism, is Whewell's philosophy beginning to receive the hearing it deserves (see Popper, K. §§2-3).

2 Theory of science

Whewell's theory of science is presented in the *Philosophy* as an argument from a theory of the sources of knowledge to a detailed description of well-developed science. Somewhat systematized, it comprises the following four theses:

(1) *The Fundamental Antithesis*. Convinced that neither the empiricists, who sought to base all knowledge on experience alone, nor the intellectualists, who based science on a priori ideas, could adequately account for the development and accomplishments of science, Whewell proposed a bold alternative: all knowledge necessarily incorporates an objective element given by the world, informed and structured by conceptions furnished by the mind (which are refined during scientific research to describe the world as it is). Even the most commonplace perception must go beyond mere sensation. To perceive requires a singling out of sensation, a retention of it by the mind, and some awareness of its relations to other sensations past and present - none of which can be given by sensation alone. All knowledge thus embraces an antithesis of irreducible opposites: things as opposed to ideas, sensation as opposed to conception, fact as opposed to theory. And yet, Whewell notes, it is a 'Fundamental Antithesis of Philosophy', one that can only be reflected upon theoretically. In practice no item of real knowledge can be fully resolved into its primordial factual and conceptual ingredients; so Kant's conclusion is unavoidable: the purely substantial is unknowable in itself (see Kant, I. §5).

(2) *Theory of 'Induction'*. From the near-Kantian epistemology of the Fundamental Antithesis, Whewell goes on to argue for a theory of the acquisition of knowledge thus construed. He termed the process 'induction', but meant something quite different from all current uses of the word. Whewell envisaged induction as a corrective hermeneutic process of reading meaning, structure, regularity and law *into* the facts, rather than gleaning such information *from* the empirical data. If all items of real knowledge comprise facts, unconnected in themselves and 'colligated' by concepts furnished by the mind, it follows that new knowledge is obtained exactly when a new concept, suggested by the mind, is successfully 'superimposed' upon formerly known but seemingly unrelated facts. His language notwithstanding, Whewell was an outspoken anti-inductivist.

(3) *Theory of Excellent Science*. A well-formed science takes shape in the course of repeated 'inductions' of ever higher generality that yield a series of nested, hence deductively related, conceptual colligators. According to Whewell, the conceptual component of each such science is governed by a 'Fundamental Idea', such as that of space for geometry, force and matter for dynamics, or life for biology. As work progresses certain features of the science's Fundamental Idea gradually come to light and are formulated as axioms considered to be true *of* the Fundamental Idea. Ideally, a science will consist of an entire corpus of fact perfectly colligated by such a fully axiomatized conceptual scheme.

(4) *Theory of Truth*. Lastly, such a view of science inevitably yields a two-pronged theory of scientific truth. This is because the propositions comprising a scientific theory strive to attain two different, and *prima facie* independent forms of perfection: to be on the one hand well-formed theorems of a well-formed system of ideas, and at the same time perfect colligators of fact. In the role of colligator a proposition may at best be considered empirically true, while as a theorem of a well formed system of ideas, it may be considered necessarily true *of the science's Fundamental Idea* - acknowledged to the point that *within the system* one cannot distinctly intuit its negation. Whewell's contention that a proposition may thus be considered necessarily true (of a Fundamental Idea) and yet eventually prove empirically false, has baffled many of his critics. Truth within a conceptual scheme only implies that the proposition in question is conceived to be true of a Fundamental Idea (and hence must necessarily hold each time the Idea is applied to facts). But whether or not it is also true of the facts is forever contingent upon empirical test. Whewell's notion of truth within a conceptual scheme thus defies Kant's celebrated taxonomy. Since he insisted that a truth relation (other than mere coherence and resting on more than formal definitions) obtains within pure systems of ideas (as in pure mathematics) it cannot be considered merely analytic. On the other hand, although a priori with respect to the facts, such truths cannot be considered synthetically true prior to independent empirical test.

3 Methodology

Whewell's methodology falls under three major headings corresponding to the stages preceding, during and following scientific discovery. This part of his philosophy is largely anticipated in the *History*, in which major scientific breakthroughs are broken down into 'inductive epochs', their 'preludes' and their 'sequels'.

Whewell considered discovery itself reducible to no more than an imaginative 'happy guess', a 'felicitous and inexplicable stroke of inventive talent' defying methodological prescription. Like Popper almost a century later, Whewell called upon scientists to hypothesize freely, fancifully and frequently. Bacon's condemnation of 'anticipation', and Newton's '*Hypotheses non fingo*', he urged, expressed the wrong attitude. He refused, however, to view scientific conjecture as entirely capricious. By 'decomposing' the facts in hand as far as possible into their conceptual and factual ingredients, he argued, a part of the science's conceptual scheme, at least that to which the facts in hand directly pertain, may be (re)constructed. Such (partial) knowledge of a science's conceptual history can provide discoverers with the appropriate setting and idiom for their new conjectures.

But bold speculation will lead to real knowledge, he argued further, only if firmly coupled to an 'ingenuity and skill which devises means for rapidly testing false suppositions as they offer themselves'. The 'Popperian' ring is again unmistakable: the worth of a conjecture is measured not by reports of favourable data, but by its proven resistance to falsification.

Resilience in the face of prudent testing, however persistent, Whewell observed, cannot be considered conclusive proof of the actual (empirical) truth of a hypothesis. And yet he maintained that truth lies within the reach of science. True theories distinguish themselves from merely good ones on two related accounts. First in repeatedly

exhibiting what he termed ‘consilience of inductions’, or explanatory surprise. And second, in generating ‘progressive simplification’ as they are repeatedly applied to new and different kinds of phenomena. In Whewell’s opinion both gravitation theory and the undulatory theory of light had proved themselves true in this manner. Both criteria are as questionable (as criteria of truth) as they are intriguing (as criteria of acceptability), and have attracted considerable attention.

Whitehead, Alfred North (1861-1947)

Whitehead made fundamental contributions to modern logic and created one of the most controversial metaphysical systems of the twentieth century. He drew out what he took to be the revolutionary consequences for philosophy of the new discoveries in mathematics, logic and physics, developing these consequences first in logic and then in the philosophy of science and speculative metaphysics. His work constantly returns to the question: what is the place of the constructions of mathematics, science and philosophy in the nature of things?

Whitehead collaborated with Bertrand Russell on Principia Mathematica (1910-13), which argues that all pure mathematics is derivable from a small number of logical principles. He went on in his philosophy of science to describe nature in terms of overlapping series of events and to argue that scientific explanations are constructed on that basis. He finally expanded and redefined his work by developing a new kind of speculative metaphysics. Stated chiefly in Process and Reality (1929), his metaphysics is both an extended reflection on the character of philosophical inquiry and an account of the nature of all things as a self-constructing 'process'. On this view, reality is incomplete, a matter of the becoming of 'occasions' which are centres of activity in a multiplicity of serial processes whereby the antecedent occasions are taken up in the activities of successor occasions.

1 Life

Alfred North Whitehead studied mathematics at Trinity College, Cambridge. In 1884 he became a Fellow of Trinity, where he taught mathematics, Bertrand Russell and J.M. Keynes being among his pupils. He was a liberal in politics and an advocate of women's rights. He wrote*Principia Mathematica* (1910-13) with Russell, moving to London in 1910, where he taught mathematics at University College and was active in educational reform. He became Professor of Applied Mathematics at the Imperial College of Science and Technology in 1914, thereafter writing on the philosophy of science. In 1924 he took up a chair in philosophy at Harvard, where he produced a series of works in speculative metaphysics.

Whitehead's work falls into three periods: the early period of mathematics and logic, the middle period concerned with the philosophy of science; and the late period of speculative metaphysics. Although a matter of debate, his philosophical development is best seen as a shifting, ever-widening analysis of the concept of construction (see Constructivism §1; Constructivism in mathematics §6).

2 Mathematics and logic

Whitehead's three main early works indicate the central role played by mathematics, logic and science in shaping the themes and models which inform his philosophical thought. His first book, *A Treatise on Universal Algebra: With Applications* (1898), develops Grassmann's work in what was then the new field of abstract algebra. Although it had little influence on the subsequent development of mathematics, the *Treatise* has at least three philosophically significant features.

First, it is concerned with the 'universalization' or 'generalization' of variables beyond their traditional restriction as symbols for numbers. Generalization takes the form of 'substitutive schemes', which at this stage in Whitehead's career are non-axiomatized algebraic formulae having the status of a calculus which symbolizes the operations of addition and multiplication. He holds that the construction of substitutive schemes involves some (here unspecified) relation to the empirical world and that, to be significant, such schemes must have applications or substitutions in some field. In turn, application assists in the investigation of the schemes themselves, which have heuristic value even if they are only partially interpretable at a given stage of knowledge.

Second, alongside the emphasis on empirical connection and a realist concern with the significant application of schematized structures, a strong formalist tendency is evident in the *Treatise*: while consistency is repudiated as the sole ground for existence-theorems, mathematical schemes are defined as conventional idealizations independent of perceptual content (see Realism in the philosophy of mathematics §2). Third, however, Whitehead also emphasizes the synthetic processes of intellectual construction involved in mathematical inference. Like the mathematical intuitionists later on, he regards '$2+3$' and '$3+2$' as nonidentical (see Intuitionism §1); he holds that the difference of order directs different processes of thought and that equivalence is a matter of identity-in-difference.

The development of a philosophy which would coherently relate the different orientations - realist, formalist and intuitionist - evident in the treatment of construction in his mathematical writings is a central concern of Whitehead's subsequent thought.

Whitehead's Royal Society memoir On Mathematical Concepts of the Material World (1906) offers different logical schemes or models for different theories of the structure of the physical world. As later in *Process and Reality* (1929), Whitehead employs the axiomatic method in constructing a scheme and defines a scheme as a hypothesis to be assessed on the principle of Ockham's razor (see William of Ockham §2): the preferred scheme in the memoir is that which posits only one class of ultimate entities. He anticipates his later thought by criticizing the Newtonian account of nature as composed of externally related atoms each occupying a position in absolute space at an absolute time (see Mechanics, classical §§1, 4-5; Newton, I. §§3-4). His preferred scheme is constructed on the model of electromagnetic theory in terms of the flux of energy. The ultimate entities are complexes of relations: points are classes of linear relations which can be given an empirical interpretation in terms of vectors or lines of force. The emphasis is on a logic of relations as a way of uniting permanent structure and change in one schematized serial order - an issue which occupied Whitehead for the rest of his career.

Principia Mathematica (1910-13), written in collaboration with Russell, (see Russell, B. §3) is best seen as an account of the logic of relations and an attempt to develop as far as possible the hypothesis of 'logicism' - the claim that all pure mathematics can be derived from an axiomatic scheme of logical concepts taken as primitive (see Logicism §4). The effect of the difficulties which subsequently emerged in the logicist project was to strengthen the mathematical-intuitionist tendencies in Whitehead's thought: he later treats Gödel's incompleteness theorem as indicating that mathematical logic is an instance of the finite character of all constructions (see Gödel's theorems §§3-5).

3 Philosophy of science

Whitehead's philosophy of science analyses the ontological status of scientific and mathematical concepts in terms of their derivation from the elements and relations of nature as disclosed in sense-experience. He abandons the Newtonian concept of 'nature at an instant' and rejects the 'bifurcation' of nature into perceived qualities and the theoretical entities of science (such as electrons), in particular Russell's phenomenalist view of theoretical entities as constructions out of atomic sense-data. The new theories of physics, the new logic of relations and Bergson's account of the fluidity of nature are seen as making possible an empiricism which is neither representationalist nor phenomenalist. Logical constructions and perceived qualities are to be analysed as features of 'one system' of multiple relations by means of a redefinition of sense-experience as the disclosure of the 'passage of nature', that is, of occurrences or events with spatiotemporal spread.

'Events' are one of the two basic constituents of nature that Whitehead holds to be disclosed in sense-experience. Taking the place of traditional concepts of substance, events are unrepeatable, relational entities which overlap or extend over one another (see Substance §3). Their nature as spatiotemporal regions, however, expresses only some of the features of this fundamental relation of extension, for Whitehead also terms it 'process' and 'creative advance'. Events thus imply a special kind of activity pointing towards the later, speculative account of reality as 'creativity' (see Events).

'Objects' are the second basic constituent of nature disclosed in sense-experience. Objects take the place of universals: they are repeatable characters or properties which are neither Platonic forms nor nominalist resemblances but, as 'ingredients' in events, are like Aristotelian *universalia in rebus* (see Aristotle §15; Universals §1). However, objects do not act and do not stand to events in an invariable two-termed relation of predication; they are terms in a multiple relation of 'ingression'. Thus a 'sense-object' - for example, a colour which is perceived as situated in an event - involves multiple relations between the percipient event (the relevant bodily state of the observer), the event which is the situation of the object, and the conditioning events relating the percipient event to the situation. As this multiple relation is a facet of nature, the perspective relative to the percipient event is not 'outside' the world but belongs to the world in that relation, thereby dissolving the duality of 'subjectivity' and 'objectivity'. Scepticism is never an issue for Whitehead, as scepticism assumes that duality has fundamental metaphysical status (see Scepticism §1). His complex account of different types of objects is replaced in his later work by an account of the relation of what he calls 'eternal objects' to the becoming of

‘occasions’.

What Whitehead called his ‘Method of Extensive Abstraction’ is primarily an application of a constructivist logic of classes to the question of the status of such theoretical entities as instants of time and points in space. Instants and points are routes of approximation across, respectively, the durations of events and spatial volumes, which are arranged in a continuum of whole and part like a nest of Chinese boxes. As we descend in the series we progressively reach durations and volumes of ever smaller extension. Instants and points are sets or classes of the whole - part relations of the durations and volumes which enclose them.

Whitehead’s attempt to unify space, time and matter in a single system of relations led him to address Einstein’s theory of relativity critically. He agrees with Einstein that space and time are abstractions from spacetime events and that there is an infinite plurality of different ‘time-series’. However, Whitehead’s analysis of the perceptual relations between events allows him to maintain the objectivity both of the distinction between space and time for the observer and of the relative position of the observer. Further, the problems of rotation, incongruent counterparts and the application of geometries lead him to give the passage of events its own internal, uniform (homoloidal) spatial structure, independent of any relation to the objects of which they are the situations, and he treats that structure as actual. This brings him into conflict with the general theory of relativity in which spacetime varies with its (material) contents (see Relativity theory, philosophical significance of §2).

4 Speculative metaphysics

Whitehead’s speculative thought challenges the critique of metaphysics characteristic of twentieth-century Anglo-American and European philosophy. In contrast to Russell and his successors who interpret modern mathematical and logical developments in the context of a weak theory of being or existence as quantification, Whitehead sees these developments as reopening the possibility of a strong theory of being or existence as ‘act’ (see Being §4; Existence §2). Like Bergson and the later Heidegger (see Heidegger, M. §2), Whitehead defines the act of being in terms of finite self-actualization, independent of any metaphysically complete cause or ground; but unlike them, he regards self-actualization as rationally analysable.

There is no longer any foundationalist appeal to sense-experience in Whitehead’s metaphysics (see Foundationalism §1). The subject matter of his ‘speculative scheme’ is the ‘empirical side’ of the analysis, defined as everything of which we are conscious as historically situated beings. The construction of an axiomatized scheme of categories is a matter of ‘imaginative generalization’: significant features of the historical world are employed as analogues for the analysis of the nature of all things. The cogency of the categories depends upon the range of their ‘substitutions’ or ‘applications’ on the ‘empirical side’. Categories and applications stand in a relation of proportional analogy (as A is to B, so C is to D).

As a ‘generalized mathematics’, Whitehead’s speculative scheme of categories can be epitomized as universalizing the mathematical concept of series and as closely akin to the mathematical intuitionists’ theory of number construction. The self-actualization of all things is interpreted as a finite series of acts of self-construction which are asymmetrical, transitive and irreflexive, constituting an iterative, infinitely proceeding multiplicity of sequences. This is the ‘process’ of ‘actual [that is, actualizing] entities’, or ‘actual occasions’ which constitute the ‘one genus’ by which the scheme aspires to describe everything. Whitehead terms the scheme ‘the philosophy of organism’ to indicate that it embraces biology as much as physics and constitutes a theory of the ‘experience’ of all things as self-constructing centres of activity (see Processes §4).

Whitehead’s complex analysis of the serial process of the becoming of occasions employs a variety of analogies with ‘mentality’, ‘feeling’ and the vectorial transfer of energy. Although they do not overlap, there are no ‘single’ occasions, for occasions are relational or serially constituted entities in two senses. First, the completion of an occasion in a series of occasions is its ‘objectification’ by successor occasions. Second, a successor occasion has its own internal serial structure as a self-constructing synthesis or ‘concrescence’. The relation of freedom and determination simply depends on an occasion’s complexity of response, allowing it to modify the extent to which it is determined by its predecessors and environment.

Whitehead’s theory of eternal objects or ‘pure potentials’ is modelled on that of the propositional function. However, the theory does not grant the propositional function any metaphysically primitive status but explains what makes the propositional function possible. In the state of ‘general potentiality’ eternal objects do not form an

infinite class of possibilities, but a ‘matrix’ of the ‘multiplicity’ of the endlessly nested possibilities which finite actualizations afford. As components of predecessor occasions which are objectifiable by successor occasions, eternal objects have the status of ‘real potentiality’. Potentiality and actuality are defined as relations of seriality, states or stages of actualization, which stand in a strictly functional relation of satisfaction and not in any of the traditional relations of agency, resemblance or imitation.

Eternal objects of a special kind, ‘the objective species’, constitute the ‘extensive continuum’ or abstract system of part and whole relations. The key philosophical difference with Whitehead’s middle-period extension is that the extensive continuum is potential, not actual, and is actualized by the becoming of occasions. Mathematical relations can thus be intuitionistically defined as equivalently ideal and real, potential and actual: that is to say, they are definable as states or stages of serial actualization.

Whitehead’s scheme of categories has a number of significant applications, some of which can be summarized here.

Epistemological Realism. By serializing occasions, Whitehead would reconcile the claim that knowledge is perspectival or ‘situated’ with the claim that knowledge is to be defined in terms of objects distinct from and independent of the subject or concrescent occasion.

Relations. Whitehead would dissolve the opposition between F.H. Bradley and Russell on relations by interpreting the doctrines of internal and external relations in the context of his serial pluralism (see Bradley, F.H. §§4-5): a successor occasion is internally related to its antecedent occasions, but its antecedent occasions (as completed or ‘perished’) are not internally related to it. Internal and external relations are thus states or stages of seriality.

Perception. The primary mode of perception is not a matter of distinct impressions or sense-data but, under the principle of serial connection, is the direct experience of the ‘causal efficacy’ of the antecedent world. The other mode of perception is ‘presentational immediacy’, which is the presented locus or spacetime region of the percipient occasion. The two are combined in an adverbial theory of sensation.

God. Whitehead does not attempt to prove God’s existence but to show that, contrary to the views of many theorists of finite self-actualization, there is nothing to prevent the redefinition of the concept of God in that context. Thus eternal objects in their state of ‘general potentiality’ are ‘termed’ God because of the ultimate, underivable character of possibilities of structure: as the final principle of determination, the concept of God is their nearest conceptual correlate. Similarly, ‘real potentiality’ can be said to be derived from God because the experience of potentiality from an occasion’s standpoint is nothing other than the ultimacy of ‘appetition’ for actualization. Interpreted as God, these aspects are termed his ‘primordial nature’ and revise the concept of God as creator: he does not create occasions but provides them with potentiality. In his ‘consequent nature’ God objectifies and transforms occasions in the eternal harmony of his nature. As a nontemporal being, God is an ‘actual entity’, not an occasion, but his primordial and consequent natures define him as a component of serial process. This ‘dipolar’ nature expresses the way in which the scheme has a place for the concept of God as both first cause and redeemer (see Process theoism).

Speculative Analysis. Whitehead’s general strategy is to define ideality and reality, not as fundamental metaphysical opposites, but as states or stages of the serial process of self-construction. While his universalization of the concept of finite or serial construction makes him a speculative realist, his metaphysics is also self-referentially inclusive, that is, the metaphysical scheme is an instance of finite or serial intellectual construction which as such is not subject to the law of the excluded middle (see Intuitionistic logic and antirealism §1). The scheme can thus be regarded as real inasmuch as it is constructed or applied, and ideal or hypothetical inasmuch as it is finite and revisable and consequently does not exclude alternative analyses. While most readers of Whitehead interpret his speculative realism to mean that his categories are accounts of the metaphysical contents of the world, one can also regard them as conditions of the contents of the world, that is, as transcendental categories of a new kind which are neither real in the medieval sense nor ideal in the Kantian sense, but fallible, historically situated constructions, formulating the ultimate generalities which constitute the nature of things.

JAMES BRADLEY

List of works

Whitehead, A.N. (1898) *A Treatise on Universal Algebra: With Applications*, Cambridge: Cambridge University Press.(A pioneer work in the field of abstract algebra.)

Whitehead, A.N. (1906) On Mathematical Concepts of the Material World. Philosophical Transactions of the Royal Society of London, Series A, in F.S.C. Northrop and Mason W. Gross, *Alfred North Whitehead: An Anthology*, Cambridge: Cambridge University Press, 1953, 11-82.(This book contains extensive extracts from Whitehead's main works.)

Whitehead, A.N. and Russell, B.A.W. (1910-13) *Principia Mathematica*, Cambridge: Cambridge University Press, 3 vols; 2nd edn, 1927.(One of the central works in modern logic and the philosophy of mathematics.)

Whitehead, A.N. (1911) *An Introduction to Mathematics*, London: Williams & Norgate; repr. Oxford: Oxford University Press, 1948, 1958, 1969.(A clear, elegant account of the basic elements of modern mathematics.)

Whitehead, A.N. (1917) *The Organization of Thought*, London: Williams & Norgate, and Philadelphia, PA: J.B. Lippincott.(This collection of papers, with others presented to the Aristotelian Society between 1916 and 1923, notably 'Uniformity and Contingency' (1922), is reprinted in A.H. Johnson (ed.) *Alfred North Whitehead: The Interpretation of Science*, New York: Bobbs-Merrill, 1961.)

Whitehead, A.N. (1919, 1925) *An Enquiry Concerning the Principles of Natural Knowledge*, Cambridge: Cambridge University Press.(The second edition of 1925, with additional notes, should be consulted.)

Whitehead, A.N. (1920) *The Concept of Nature*, Cambridge: Cambridge University Press, 1993. (A nontechnical analysis of the philosophy of science and nature which Whitehead sees as required by physics.)

Whitehead, A.N. (1922) *The Principle of Relativity*, Cambridge: Cambridge University Press; philosophical sections repr. in Whitehead (1906).(A critical analysis of the theory of relativity from the point of view of Whitehead's philosophy of science.)

Whitehead, A.N. (1925) *Science and the Modern World*, New York: Macmillan, and Cambridge: Cambridge University Press, 1926; New York: The Free Press, 1967.(A critical history of the development of modern science, concentrating on the concept of organism as the basic principle of modern scientific thought.)

Whitehead, A.N. (1926) *Religion in the Making*, New York: Macmillan, and Cambridge: Cambridge University Press, 1926; New York: Meridan, 1974.(A historical and critical reflection on the nature of religion in the light of Whitehead's metaphysics. References are usually to this or the Cambridge edition.)

Whitehead, A.N. (1926) *Symbolism, Its Meaning and Effect*, Cambridge: Cambridge University Press; New York: Macmillan, 1927; London: G.P. Putnam's Sons, 1959.(A clear statement of Whitehead's theory of perception, later elaborated in *Process and Reality*.)

Whitehead, A.N. (1929) *The Aims of Education and Other Essays*, New York: Macmillan, and London: Ernest Benn, 1929; New York: The Free Press, 1967.(This work is essentially a shorter version of *The Organization of Thought*.)

Whitehead, A.N. (1929) *The Function of Reason*, Princeton, NJ: Princeton University Press, 1929. Boston, MA: Beacon Press, 1958.(A prolegomenon to *Process and Reality*, this work presents philosophy as a matter of the creation of novel concepts.)

Whitehead, A.N. (1929) *Process and Reality: An Essay in Cosmology*, New York: Macmillan, and Cambridge: Cambridge University Press; corrected edn, with comparative readings and detailed index, by D.R. Griffin and D.W. Sherburne, New York: The Free Press, 1978. (Whitehead's central work in speculative metaphysics, presented in axiomatized form with extensive applications.)

Whitehead, A.N. (1933) *Adventures of Ideas*, New York: Macmillan, and Cambridge: Cambridge University Press; New York: The Free Press, 1967.(An analysis of the concepts of civilization and history from the standpoint of Whitehead's metaphysics, this work includes a clear statement of his position and a redefinition of the 'transcendentals' of medieval philosophy.)

Whitehead, A.N. (1938) *Modes of Thought*, New York: Macmillan, and Cambridge: Cambridge University Press; New York: The Free Press, 1968.(A rich and suggestive restatement of Whitehead's metaphysics, clearly underlining his mathematical intuitionist orientation.)

Whitehead, A.N. (1947) *Essays in Science and Philosophy*, New York: The Philosophical Library. (An important collection of papers, including some of Whitehead's clearest programmatic and methodological statements, notably 'Uniformity and Contingency', 'Analysis of Meaning', 'Process and Reality' and 'Mathematics and the Good'.)

Woodbridge B.A. (ed.) (1977) *Alfred North Whitehead: A Primary-Secondary Bibliography*, Bowling Green, OH: Philosophy Documentation Center, Bowling Green State University.(A complete bibliography of Whitehead's works and the secondary literature up to 1977, totalling 1,868 entries.)

Will, the

As traditionally conceived, the will is the faculty of choice or decision, by which we determine which actions we shall perform. As a faculty of decision, the will is naturally seen as the point at which we exercise our freedom of action - our control of how we act. It is within our control or up to us which actions we perform only because we have a capacity to decide which actions we shall perform, and it is up to us which such decisions we take. We exercise our freedom of action through freely taken decisions about how we shall act.

From late antiquity onwards, many philosophers took this traditional conception of the will very seriously, and developed it as part of a general theory of specifically human action. Human action, on this theory, is importantly different from animal action. Not only do humans have a freedom of or control over their action which animals lack; but this freedom supposedly arises because humans can act on the basis of reason, while animal action is driven by appetite and instinct. Both this freedom and rationality involve humans possessing what animals are supposed to lack: a will or rational appetite - a genuine decision making capacity.

From the sixteenth century on, this conception of the will and its role in human action met with increasing scepticism. There was no longer a consensus that human action involved mental capacities radically unlike those found in animals. And the idea that free actions are explained by free decisions of the will came to be seen as viciously regressive: if our freedom of action has to come from a prior freedom of will, why shouldn't that freedom of will have to come from some yet further, will-generating form of freedom - and so on ad infinitum?

Yet it is very natural to believe that we do have a decision making capacity, and that it is up to us how we exercise that capacity - that it is indeed up to us which actions we decide to perform. The will-scepticism of early modern Europe, which persists in much modern Anglophone philosophy of action, may then have involved abandoning a model of human action and human rationality that is deeply part of common sense. We need to understand this model far better before we can conclude that its abandonment by so many philosophers really was warranted.

1 The will and rational action

Talk of an individual's will may mean simply what actions they are motivated to perform. In this sense any performer of actions, or *agent*, has a will. But talk of the will has served more specifically to pick out the motivations of those action performers who are *rational agents*.

Suppose that there are rational justifications for performing some actions rather than others - justifications which come from a practical or action-governing reason. Then a rational agent is an agent who has the capacity to come to recognize these requirements, and then apply them.

Not all agents need be rational agents. To be a rational agent, one needs, first, a practical intellect or deliberative capacity to form practical judgments about what actions are rationally justified; and second, one needs an executive capacity to apply these judgments in one's actions. Animals, in particular, have often been seen (by Aquinas, for instance) to lack practical intellect. They supposedly have no conception of a justification for action, and so act simply on the basis of appetite.

Notice that rational agents, on our definition, can act irrationally, through defective use of their deliberative and executive capacities. They might make a deliberative mistake as to what actions are justified, or (though this possibility is controversial; see Akrasia) the defect might be purely executive, in their deliberate performance of an action despite their judgment of this action as unjustified.

Someone who does count as a rational agent can be said to possess a *rational appetite* - a capacity to become motivated to act through rational decision making, thereby forming intentions to act, decisions and intentions based in turn on their deliberations about what actions would be justified. Talk of a faculty of will has typically served to pick out this rational appetite or decision making capacity. *Intellectualists*, most famously Thomas Aquinas, see the will as tied to the practical intellect, decisions to perform a particular action occurring through a practical judgment that that action should be performed. Accordingly, any freedom of decision must derive from a freedom of the practical intellect (see Voluntarism). Whereas, flourishing after Aquinas, *voluntarists* maintain that the will has a freedom independent of the practical intellect. One might even decide, irrationally, to perform an

action despite judging its performance to be unjustified.

Medieval and early modern scholasticism produced highly developed theories of human agency as involving the will. Thus Aquinas saw intentional or deliberate human action as generally involving the exercise of the will: when I intentionally move my hand, that action arises out of my willing my hand to move. And Aquinas thought this because, in his view, a truly deliberate action must arise from a capacity to respond motivationally to rational requirements attendant upon action - in other words, from an exercise of the rational appetite. Animal action could not be intentional as ours is, precisely because animals lack this rational motivational capacity.

Furthermore, Aquinas conceived the exercise of the will to be itself a case of action. The *first-order* agency of ordinary actions such as deliberately raising one's hand, was to be explained in terms of a *second-order*, action-generating agency of the will. Why see the willings or decisions to act which, allegedly, explain our actions as being actions themselves? A key assumption is that action in its distinctively human, fully intentional form, consists in agents conforming to or violating requirements of practical reason. 'An act is [fully] voluntary when it is an operation of reason' (*Summa theologiae* Ia IIae, q.6 a.1). On this *practical reason-based* view of human agency, to act is to exercise our rationality, whether competently or defectively, in a distinctively practical way. And this we do, in particular, in the decisions by which we motivate ourselves to perform this action rather than that. For whether we count as conforming to or violating practical reason does indeed plausibly depend on which actions we decide to perform (see Aquinas, T. §12).

Wherever a conception of human agency as essentially the exercise of practical rationality has remained compelling, so theorists have been inclined to characterize ordinary human actions, such as intentional hand-raisings, as involving an inherently intentional, action-motivating agency of the will. How more precisely the will is conceived then greatly depends on the accompanying conception of our practical rationality. Thus Kant, holding practical reason to be the legislation of all rational agents, conceived the will partly as *Wille*, a capacity for autonomous legislation, and partly as *Willkür*, an executive, action generating capacity that was itself exercised freely. Deliberate human agency, whether rational or irrational - whether conforming to *Wille* or not - generally involved the operation of *Willkür*.

Did the Greeks entertain analogously will-based theories of human agency? Only rational humans, according to Aristotle, can act on the basis of *prohairesis*, or a rational choice based on deliberation about how it would be good to act (see *Nichomachean Ethics*, Book III). Aquinas took Aristotle's prohairesis to be equivalent to his own *electio* or decision of the will; but mistakenly, since Aquinas' decision of the will was supposed to be a general feature of intentional human action, whereas for Aristotle only some such human action was prohairetic: intentional human agency could also occur without involving a distinctively rational appetite.

Stoicism did develop a more truly will-involving conception of human agency. While animal action was seen as simply driven by impulse, humans were considered to have a rational capacity for *sunkatathēsis* - a capacity for judgmental assent to, or dissent from, a given action - which capacity was believed essential to our deliberate agency. Thus humans had control over what actions they assented to. The voluntary was thought to begin then at the point where, through *sunkatathēsis*, we motivated ourselves to perform a given action (see Stoicism §12).

2 The will and the free will problem

The free will problem can arise as a strictly ethical problem about our moral responsibility for our actions: under what conditions can we genuinely deserve morally based reward or blame for what we do? (See §3.) But the free will problem can also arise as a problem, not immediately ethical, about freedom of action - about whether we possess genuine control of how we act, in the sense of possessing a freedom to act otherwise than as we actually do: is it really up to us which actions we perform?

It is nowadays sometimes assumed that, as a problem about action, the free will problem has nothing much to do with the will. But this is a mistake, as our ordinary intuition about freedom of action suggests. It is up to us which actions we perform only because we are capable of taking decisions about how we shall act, and it is up to us which actions we decide to perform. Is not that a claim about our freedom to which we naturally assent? If so, then our ordinary conception of our freedom is *psychologizing*: that is, the freedom of our first-order action is held to depend on our possession of a prior, psychological analogue of that freedom located in a second-order agency of the will.

We have seen that the idea that we have a capacity for a second-order agency of the will at all - that the decisions which explain our actions are actions themselves - comes with a practical reason-based conception of our agency: human action consists in the exercise of practical rationality. It is plausible then that our psychologizing conception of our freedom of action is likewise to be explained in terms of some connection between freedom of action and practical rationality. A widely believed condition of possessing freedom of action, after all, is that one have a capacity for practical rationality. Free agents must be able to exercise their control over their actions in a reason-applying way. Animals such as sharks or mice are not free to act otherwise than as they do, precisely because they are not plausibly rational agents. Perhaps this connection between freedom and practical rationality can explain why freedom of action should depend on a freedom of the will in particular.

One way this explanation might work is if we suppose that free agents must indeed be able to exercise their control over their actions in a reason-applying way. How then does practical reason recommend actions to us? Plausibly it does so in the form of plans, or sequences extending through time. When we deliberate about how to act, we are almost invariably deliberating between rival *plans* or sequences of action extending into the future, our performance of which as a whole depends on our continuing motivation into the future. And that is because how we act in the present generally only has value for us on the assumption that we do go on to perform further appropriate actions in the future. Saying a given word now generally only has value if we do go on to utter the other words composing our message. Stepping out of the door now only has value if we do continue walking to the supermarket thereafter. The unit of practical reason - the form in which actions have value for us, and so the form in which we deliberate about them - is the plan.

So to exercise action control in a reason-applying way, we need to exercise control over whole plans, and so over sequences of action extending into the future. Without plan control, as we just saw, we should at any given time lack control over such elementary matters as what we communicated, or where we shopped: for such depend on which plans we execute. Now such plan control can only come from some controlled doing in the present, available to us as rational deliberators, by which we can determine which future actions we shall be performing. And deciding to act looks as though it is precisely the doing required. By deciding on a given plan of action, we can ensure that we thereafter remain motivated to execute it, so that we do act as we have deliberated we should. That is why our decisions can often leave us and others knowing in advance that we shall indeed be acting as we have decided. Decision making can give us plan control, provided of course that taking a particular decision to act is indeed something that we deliberately do, so that we can have control over which actions we decide to perform. Given free will, decision control gives us a capacity for rational self-determination - for controlling our actions in the form in which they matter to us as rational agents. And that is a capacity which free agents plausibly need.

3 The will and ethical theory

Does being a morally responsible agent require any special capacity of will, beyond even that required for being a rational agent?

Thomas Nagel has claimed that there is an aspect of common sense morality which excludes luck: someone's moral goodness or conformity to moral requirements must not depend on any factors which are outside their control, or for which they are not morally responsible. Yet people's ordinary first-order actions and their consequences do seem to depend on luck. Whether, for example, a given person ever manages to help others must depend on matters for which they may well not be responsible, such as the presence of others needing help, and their own possession of the skill and resources to provide the help (see Moral luck).

The only capacity for action that could ever be independent of luck seems to be the second-order action of one's will - of one's decisions to perform first-order actions. For whether or not others are around to be helped, and whether or not one could help others if one tried, one can still take an advance *decision* to help others should the need arise and should one be able to help. It is in such inner decisions of the will, then, that the moral life must be lived: moral obligations are obligations on the will; and it is solely through the agency of one's will that one can count as virtuous or morally good.

However, perhaps even the actions of the will are not really independent of luck either. What decisions I take depends on my education and upbringing, matters of luck too. The doctrine that morality excludes luck is arguably a sceptical view, that prevents morality applying to any empirical agents like us.

But there is a quite different view which also implies moral obligations on the will. *Virtue legalism* is the view that the moral life involves conformity to a moral law containing obligations; and that, in particular, we are under an obligation to be virtuous or morally good.

Now moral goodness does seem to depend, not on our ordinary first-order actions and their consequences, but on the motivation behind those actions. The morally good person is not the person who actually helps others, but rather the person who is motivated to help others if they can. One's moral goodness reflects, after all, how far one is swayed to appropriate first-order action by morally relevant considerations, such as the needs of others. It follows then, that an obligation to be morally good is an obligation to be motivated to perform certain first-order actions.

Now one very natural view is that the only proper object of obligation is action, or refraining from action. We can only be obliged, just as we can only be commanded, to do things or refrain from doing them. We cannot be under an obligation to have things simply happen to us, independently of any action or omission on our part. Suppose then that any moral obligation must be an obligation on action; then, if moral virtue lies in being motivated to perform certain first-order actions, and this moral virtue is obligatory, it follows that such motivation must itself arise from an action-motivating, second-order agency of the will.

Virtue legalism has a long history. Writers as diverse as Abelard (1136-9) and Leibniz (1706), the Stoics and Richard Cumberland (1672), teach that the moral law is distinguished from merely human laws precisely by virtue of its demanding, not simply conformity to rules governing our external behaviour, but the right disposition of will.

Recent moral philosophy has seen a revival of the view that morality presupposes an agency of the will - but this time outside virtue legalism. David Gauthier (1986) has argued that conformity to moral obligations, say to altruism, can be rationally justified in terms of self interest. While altruistic first-order actions may not be in one's interest, the disposition to perform them may be, in that holding it secures the cooperation of others. In which case self interest makes it rational to secure that cooperation by disposing oneself - through a decision of the will - to altruism. The rationality of the disposition formation *qua* decision to act is then supposed to imply the rationality of the altruistic action decided on, should the occasion for performing it ever arise.

Gauthier's theory reveals a tension in our ordinary thinking about rationality and the will. If taking a particular decision is itself an action, then can it not be made rational, like any action, by its expected good consequences? But these expected good consequences may arise, as in Gauthier's example, independently of performance of the action decided upon. So the thought that decisions to act are actions themselves seems to imply that the rationality of a decision to act is to be determined as Gauthier determines it - in terms of the decision's consequences, and not those of the action decided upon, and so other than by reference to a prior and independent rationality attaching to the action decided upon.

But we also think that the rationality of deciding to do A *does* depend wholly on a prior and independent rationality attaching to doing A: since the function of decisions to act is to apply reason as it concerns the actions decided upon, what makes it rational to decide to do A in particular can only be the prior rationality of doing A - in which case, of course, the rationality of deciding to do A would indeed (as Gauthier also wants to maintain) imply the rationality of doing A thereafter.

The natural idea that decisions serve to apply reason as it concerns the actions decided upon is not obviously consistent with the equally natural idea that decisions are themselves deliberate actions. This is a deep and unresolved problem in our conception of rational agency and the will.

4 Scepticism about actions of the will

Scepticism about actions of the will developed when, in the early modern period, theorists abandoned a practical reason-based theory of human action, characterizing human action instead as, hitherto, animal action had been characterized - in purely motivational terms, as a product of appetite.

Something at least analogous to human action occurs in animals. We talk of animals performing actions for purposes, such as stalking in order to catch prey. But if animals are not rational agents, their actions cannot be

characterized as exercises of practical rationality. And so the same philosophers who proposed practical reason-based theories of human action, also proposed importantly different, motivation-based accounts of animal action. Animal action was merely the purposive product of appetite: it was performed simply as a believed or perceived means to desired ends, whether for its own sake or as a means to further ends. A non-rational animal's A-ing counted as its action in virtue of its being moved to A by some appetite for a given end, and a belief or perception that doing A would or might further that end.

We have here an analogue of human action, simply because so much human action is purposive in its motivation too. It is just that this motivation in humans was supposed to come from an exercise of rationality. Whereas in animals, the appetites that motivated were supposed non-rational in origin.

Notice, however, that not all human actions are purposive. Particular decisions to act, even if actions themselves, still are not taken as means to ends. My decision to do A rather than B will characteristically be based on beliefs about what ends would be furthered by *doing* A rather than B - not on the basis of beliefs about what ends would be furthered by *deciding to do* A rather than B. In deliberation we consider as means to ends, not our decisions to act themselves but the actions between which we must decide. If deciding to perform a particular action counts as a deliberate action itself, that must be because the decision counts as an exercise of practical rationality, and not because of its purposiveness.

From the sixteenth century on, we find increasing numbers of theorists characterizing all action, human and animal, in terms of a purposive motivation. And the will itself was reconceived, no longer as a distinctively rational appetite peculiar to humans, but as a simple locus of action-motivating passion found in animal and human alike. In other words, all action, human and animal alike, was characterized as a product of a will to perform it. As Hobbes put it in *Leviathan* chapter 6, 'a Voluntary Act is that, which proceedeth from the Will, and no other'. Since the willing of a particular action is not plausibly purposive itself, or willed - on any view, we do not generally take particular decisions to act on the basis of having decided so to decide - the will itself ceased to appear to be a locus of agency or freedom.

What encouraged the abandonment of a practical reason-based conception of human agency? Relevant developments in early modern thought are: (a) scepticism about human practical rationality; (b) projects of reconceiving rational human action in the same terms as animal action; and (c) scepticism about practical reason itself.

(a) Thanks to Augustine, it was generally agreed by Western Christians that Adam's Fall had seriously damaged our practical rationality. Now, on many views, fallen humans still retained some capacity for practical rationality, the will remaining a rational appetite. But the Reformation popularized a radical conception of the Fall that denied the practical rationality of fallen humanity outright. John Calvin, for example, admitted that as fallen we retained an intellect which distinguished us from the animals. We still formed rational judgments about which actions were justified. But the Fall had wholly removed our executive capacity to apply these rational judgments, which no longer affected what actions we were motivated to perform. Human action now took the same appetite-driven form as animal action, and the human will was no longer a rational appetite or locus of free agency (see Calvin 1559 Book II, Chapter 2).

(b) Unlike Calvin, Thomas Hobbes allowed that humans could still be practically rational as animals were not. However, Hobbes also wanted to develop an economical action-explanatory theory in materialist terms, characterizing rational human action in the same terms as non-rational animal action: so not as an exercise of a distinctively human practical rationality, but as a will-motivated, purposive doing. For Hobbes, human practical rationality had done nothing to transform human action into anything different in nature from animal action. Our practical rationality came with language - reasoning, in Hobbes' view, being just the reckoning of the implications of the general terms of a language. Language on this view was simply an invented tool which served to record and express action-motivating beliefs and appetites that were themselves language-independent. As language users, reasoning beings did not have either a psychology or a capacity for agency different in kind from that found in non-reasoning beings, any more than the actions of those who enjoy the invention of another communicative tool, writing, are different in kind from the actions of those who lack that tool.

(c) A final source of support for a motivation-based account of human agency is, of course, scepticism about

practical reason itself. There may seem little point in characterizing our agency as an exercise of rationality if, in fact, as Hume expressly claimed, our agency is not governed by reason at all. It is no surprise then that for David Hume, far from being a locus of rational appetition and agency, the will was simply a phenomenological marker for passion-motivated action: as he put it in the *Treatise* in 'Of liberty and necessity': 'By the *will*, I mean nothing but *the internal impression we feel and are conscious of, when we knowingly give rise to any new motion of our body, or new perception of our mind*'.

William of Auvergne (*c.*1180-1249)

Active in Paris during the third and fourth decades of the thirteenth century, when universities were emerging as centres of Western European intellectual life, William played a decisive role in the early development of high medieval philosophy. His writing reveals a familiarity with Aristotle, all of whose major works except the Metaphysics were readily available in Latin translation, and with the Islamic philosophers, most especially Avicenna but also Averroes, whose commentaries on Aristotle were just beginning to circulate. William looked back to the Neoplatonic traditions of the twelfth century, but he also looked ahead to the late-thirteenth-century Aristotelianizing that he and his contemporary, Robert Grosseteste, did so much to promote.

Born in Aurillac, France, around 1180, William of Auvergne went to Paris to study arts and then theology, in which field he became a university master in the 1220s. In 1228 he was named bishop of Paris and ex officio the ecclesiastical overseer of the university. He died in that post in 1249. His major philosophical work is a massive and sometimes rambling collection of treatises called the *Magisterium divinale ac sapientiale (Teachings on Divinity and Wisdom)*, the exact contents of which are debated but which surely included the important *De universo (On the Universe)* and possibly *De anima (On the Soul)*. Parts of the *Magisterium* date from the 1220s, but the finishing touches were applied in the 1230s and perhaps, in the case of *De anima*, shortly after 1240.

On the surface, William presented himself as a resolute defender of the largely Augustinian principles of Christian tradition (see Augustinianism) against what he saw as the alternately dangerous and absurd presuppositions of the pagan philosophers, most especially Plato and Aristotle. His metaphysics was consciously anti-Platonic, for although he accepted the exemplarist notion that the world was fashioned after archetypal ideals - which he, like Augustine, interpreted as ideas in the mind of God - he resolutely opposed Plato's preoccupation with the tenuousness of material reality. His position was manifested most clearly in semantics, where he rejected the contention that the real reference of the terms of normal speech was more directly to the archetypes than to the concrete world around us. Like Aristotle, he held that simple terms referred to real essences in the actual world (see Language, medieval theories of). Yet William's concrete realism likewise spurned the Aristotelian notion that individuals were the instantiation of universal essences particularized by material accidents. Instead, he maintained that real essences were in themselves completely particular and fully specific, so that individuals differed not just by their material accidents but also by their own individual essential cores. The idea remained an important subcurrent in medieval thought, emerging again with particular force in the post-Aristotelian metaphysics of the fourteenth century.

In his philosophy of mind, William also claimed to be setting himself against the Greek models. His metaphysics of essence ruled out Platonic reminiscence, for knowledge was of and from essences in the actual, material world. Yet he also attacked the Aristotelian notion of an agent intellect providing the mind with the forms of objects to be known. On this point he was reading Aristotle through the eyes of Avicenna (see Ibn Sina), who posited a separate agent intellect, the tenth of the celestial intelligences and immediate creator of the human mind. In contrast, William proposed an Augustine-inspired intellectual occasionalism by which the mind, naturally capable of perceiving essences directly but handicapped in the world of sin, drew from sensation the material for an almost discursive penetration beyond accidents to the essential nature. For this the mind needed no separation into active and passive functions and did not have to be made subject to material impressions from the level of sensation, but merely relied on its own dynamic capacity to grasp the objects of intelligibility. His explanation of the procedure whereby it did so depended on the Aristotelian notion of abstraction of the universal from the particular and provided succeeding thinkers with a theoretical base from which to develop the idea at length.

For all his rhetorical anti-peripateticism, therefore, William drew extensively upon Aristotelian perspectives. However, one last aspect of his philosophy of mind provided later Neoplatonizing scholastics such as Roger Bacon with reason to claim him as a defender of their view that God was the mind's agent intellect and thus its source of knowledge. In the case of knowledge of selected terms, most significantly those that entered into the first, self-evident principles of science and truth - terms such as 'true', 'good', 'whole' and 'part' - William maintained that the human intellect was indeed required to turn to God, who poured into it the formal elements of such cognition by a kind of intelligible illumination. In this restricted sense, God was the agent intellect William

otherwise so vehemently opposed; and to this degree he sowed the seeds of Augustinian illuminationism of the latter part of the thirteenth century.

In epistemology, William was more completely faithful to the emergent Aristotelianism of his day (see Aristotelianism, medieval). Knowledge of the truth was obtained by comparing a proposition to actual conditions in the external world, due account being taken for temporal determination and proper quantification. A true proposition states what actually has been, is or will be the case. He furthermore adopted the basic elements of Aristotle's apodictic theory of science, referring his readers to the classic expositions of scientific knowledge in the *Physics* and the *Posterior Analytics*. His account served along with that of Grosseteste as a primary conduit for the reception of such views in the Latin West. 'Science' was certain knowledge of universal conclusions demonstrated from even more certain premises, the whole structure being ultimately reducible to indemonstrable, sometimes self-evident, first principles. This foundationalist model was dominant throughout the rest of the Middle Ages.

However, it is important not to overlook an empiricist side to William's views on science. Like most Aristotelians of the thirteenth century, he thought science - or, in his case, that part of science not traceable to God's illuminated principles - was derived by induction from experience in the world. There is moreover in his works a dramatically non-Aristotelian notion of experience that harked back to Arabic and Hebrew lore on magic and the occult. The real 'experimenters' were for him natural magicians, whose ability to manipulate hidden forces in the natural world held out the promise of marvellous accomplishments. Here again was a theme of major importance for later scholastic thought, picked up with fervour by Roger Bacon and many of the so-called Perspectivists.

William of Auxerre (1140/50-1231)

William's career spans the decades at the end of the twelfth century and the beginning of the thirteenth century during which the newly recovered Aristotelian natural philosophy, metaphysics and ethics and the newly available works of great Muslim thinkers such as Avicenna and Averroes brought enormous energy and upheaval to intellectual culture. William's own views are traditional, owing their largest debts to Augustine, Boethius and Anselm. However, his major work, Summa aurea, is an influential precursor of the monumental systematic theological treatises that followed half a century later.

William of Auxerre (Guillelmus Altissiodorensis) was a master of theology at Paris. In 1231 Pope Gregory IX appointed him to a commission charged with correcting the works of Aristotle that had been proscribed at Paris in 1210, but William died a few months later and the commission seems never to have carried out its assignment. Of William's work, we possess only *Summa aurea (The Golden Synopsis [of Theology])* composed sometime between 1215 and 1225, and *Summa de officiis ecclesiasticis (Synopsis of Ecclesiastical Offices)*, a detailed description and explanation of the offices and liturgical practices of the church.

Summa aurea is modelled generally on Peter Lombard's *Sentences* (see Lombard, P.) Like the *Sentences*, the *Summa* consists of four books devoted, respectively, to the unity and trinity of God, the created realm (especially human beings and humanity's fall through sin), the incarnation of the Son and the redemption and reparation of fallen humanity, and the sacraments. However, the *Summa* diverges from the *Sentences* significantly in ways that point toward future developments in medieval philosophical thought and literature.

William has broad systematic and philosophical interests reflective of and sensitive to the rapidly expanding intellectual horizons of the early thirteenth century. In the prologue to *Summa aurea*, for example, William reflects on the nature of his project and the methodology appropriate to it, raising the question of the relation between faith and what he calls 'natural reasoning'. His Augustinian position is optimistic about the usefulness of what we would characterize as broadly philosophical methods in theological inquiry: one ought not to believe only what can be established by natural reasoning or expect natural reasoning to be entirely adequate for understanding divine matters, but natural reasoning can support and confirm faith, defend it against heresy and move simple-minded people toward the true faith.

The openness to philosophical reasoning and investigation expressed in the prologue goes some way toward explaining William's willingness to depart from the narrowly doctrinal and theological interests of Lombard's *Sentences* to develop systematic philosophical foundations for the theological issues he wants to address. Whereas Lombard's treatment of God (in Book I of the *Sentences*) begins with a discussion of the mystery of God's trinity-and-unity, William takes up the doctrine of the Trinity only after independent discussion of four proofs for God's existence (in the first treatise of Book I) and arguments for God's unity, simplicity and eternality (in the second treatise).

In Book III, concern for philosophical depth and systematic procedure lead William to replace Lombard's collection of assorted matters associated with the theological virtues with an enormous systematic discussion of moral issues. William begins (in treatise 10) by raising issues prefatory to a discussion of the virtues (*quaestiones praeambulae ad virtutes*). Among these prefatory issues is one concerning the nature of the good in general: 'The fourth question prefatory to the discussion of virtue is a question about the good. This must be dealt with prior to dealing with virtue because good is placed in the definition of virtue. Moreover, the good is the end of virtue, and the end is conceptually prior to what is directed toward the end' (Book III, treatise 10, ch. 4). William's discussion of the nature of the good is the seed from which grow the famous thirteenth-century treatises on the transcendentals by Philip the Chancellor, Alexander of Hales, Albert the Great, Thomas Aquinas and Bonaventure. William goes on to discuss virtue in general (treatise 11), the theological virtues (12-6), natural law (18), the political virtues (19), cardinal and other moral virtues (20-9), the gifts of the Holy Spirit (30-4) and the beatitudes (35). In all, William's treatment of these matters takes up nearly the whole of Book III (46 of its 55 treatises, 900 of the 1068 pages in the critical edition), and raises moral theory in the Middle Ages to a new level of philosophical sophistication. The immediate influence of this part of *Summa aurea* can be clearly seen in both Philip the Chancellor's *Summa de bono* and Albert the Great's *Summa de bono*.

William of Champeaux (*c.*1070-*c.*1120)

William studied under Anselm of Laon and became one of a number of famous teachers of logic, rhetoric, grammar and theology in early twelfth-century France, teachers who helped to establish the schools which eventually turned into the University of Paris. He is perhaps best known for his dispute with his young pupil Peter Abelard over the reality of universals, a debate which William lost so badly that most of his students elected to be taught by Abelard instead.

William's position on the nature of universals (genera and species) was that they were real things that were determined by accidents in much the way that some amorphous material is determined by shapes accidentally accruing to it (see Universals). Thus a highest genus, such as substance, becomes determined to its various species, such as body and spirit, by different, opposed accidents which it possesses simultaneously. Like many thinkers at this time, especially among the theologians, William accepted the Porphyrian interpretation of Aristotle's *Categories*, according to which the categories provide a 'tree-structured' classification scheme for all entities (see Porphyry). Actually there are ten different 'trees' corresponding to each of Aristotle's ten categories, and each successive 'branching' of each tree leads to more and more specific species of entities in the category in question. Each tree culminates in the individuals within the category, that is, the things that do not undergo any further 'branching' (see Categories §1).

William treated the mutually opposed differences, which create the species that immediately branch off from a genus, as accidents of that genus, and then went on to allow for individuating differences, which create the individuals that branch off from a final species and are mutually opposed accidents of that species. Just as one individual is distinguished from another individual of the same species only by characteristics that are accidental to that species, so each species under the same genus is distinguished by forms accidental to that genus. William's view encourages one to see each individual as ontologically constructed of successive layers of forms attaching themselves to a core that is like the highest genus under which the individual is subsumed.

Abelard quickly pointed out that this view defied the principle that opposites cannot simultaneously belong to one and the same thing, and that it also entailed that there were really only ten distinct things in the world, the ten highest genera, or categories. In William's view, everything turns out to be either one of those highest genera without any accidents or one of them with layered accumulations of accidental forms. Naturally, few were willing to accept such consequences, and William's form of realism ceased to be a live option among medieval thinkers once Abelard's critique became known.

According to Abelard, William also held that simple categorical sentences of the form of 'Socrates is white' had two senses, a grammatical sense and a dialectical (that is, logical) sense. The former treats the sentence as identifying Socrates with some white thing, while the latter treats it as asserting that whiteness inheres in Socrates. Although, according to William, the dialectical sense is 'higher', it is in its grammatical sense that the sentence is true or false. William's realist approach to universals is again apparent in the talk of the inherence of some property.

William's realism surfaces again in connection with the doctrine of topics. The topic or *locus* on which some argument depends for its logical force is, according to him, a thing in the world the argument is talking about. For example, the argument 'Socrates is a man; therefore he is an animal' has as its *locus* the thing 'man'. The general principle behind the argument, the *maxima*, is, 'What the species is predicated of, so also is the genus', and William interprets this as multiply ambiguous. Each conditional proposition that exemplifies the *maxima*, such as, 'If Socrates is a man, Socrates is an animal', expresses one of the *maxima*'s meanings. The *maxima* is then a kind of schema for propositions rather than a proposition itself. According to Abelard, one reason William held this was that the *maxima* could prove inferences only if it were about the things those inferences concerned. Thus again realism shapes William's logical doctrines.

This controversy over universals is the result of very divergent views of how the genera, species and differences, mentioned so frequently in the Aristotelian writings, should be interpreted. Among logicians in the late eleventh and early twelfth centuries the view that universality is consequent on linguistic signification had been gaining

converts, while among theologians there was a pronounced tendency to see universality as a feature ontologically independent of thought and language. Abelard represents the former interpretation, and William the latter. William went on from his disastrous confrontation with Abelard to become a teacher of theology and eventually Bishop of Chalons-sur-Marne.

William of Conches (*fl. c.*1130)

William of Conches - whom many historians have attached to the School of Chartres - was one of the early twelfth century's keenest commentators on Platonic texts, and wrote also on natural science. He believed in the harmony of Platonism and Christianity. He thought that the ostensibly pagan texts of Plato and his followers contained Christian truths which the interpreter needed to uncover, while Platonic (and more recent) science could help towards an understanding of the account of creation in Genesis.

Born in Normandy, William of Conches was already teaching and writing in the early 1120s and appears to have remained active until the 1150s. Where he taught is much disputed; he may have taught at Paris, but there is a little more evidence to link him with Chartres. Certainly his pupil John of Salisbury regarded him as at least the spiritual successor of Bernard of Chartres (see Chartres, School of). Like Bernard, William was a grammar teacher as well as an enthusiast of Plato, and it is around the twelfth-century conception of grammar that William's apparently diverse interests and writings cohere. Grammar involved detailed technical study of Latin (including the theoretical questions about semantics it raised) (see Language, medieval theories of). William's commentary on Priscian's *Institutiones grammaticae (Principles of Grammar)*, written when he was young, and revised by him as an old man, fulfilled this task, drawing extensively on the anonymous eleventh-century *Glosule* to Priscian.

The grammarian's work also included the detailed explanation of classical texts, and there was no clear distinction between literary and philosophical material. William is known to have glossed Juvenal, but he concentrated on Platonic works including Plato's own *Timaeus* (in Calcidius' translation), Boethius' *De consolatione philosophiae (On the Consolation of Philosophy)*, Macrobius' commentary on Cicero's *Somnium Scipionis (Scipio's Dream)* and probably Martianus Capella. The *Timaeus* and Macrobius were regarded as important sources for natural science, so it is not unexpected that William should have developed this interest independently, in his *Philosophia* and the dialogue *Dragmaticon* (between 1144 and 1149). In these works he also made use of - and sometimes combined or developed in an original way - medical and scientific sources translated from the Arabic and Greek.

By William's time, there was already a long tradition of assimilating Platonic texts by interpreting them allegorically in explicitly Christian terms (see Platonism, medieval). Indeed, at times he could simply borrow from the late ninth-century commentary on Boethius by Remigius of Auxerre. William differed from his predecessors in the thoroughness with which he applied the idea that the philosophers were using what he called *integumenta* (extended metaphors) to cloak the Christian truth. When pressed, he would admit that the pagan authors were indeed pagans and could not be trusted in everything they said, but usually he discovered a satisfactory reading.

His most daring interpretation was that which made Plato's World Soul an *integumentum* for the Holy Spirit. He shared this interpretation with Abelard, who may even have been his source. However, there is a revealing difference between the two thinkers' approaches. The identification was controversial because it could be taken to suggest that the Holy Spirit is lower than the other two persons of the Trinity. For Abelard, this had important implications about the knowability of God and the soundness of pagan virtues, which made it impossible for him to give up this identification. By contrast, William is willing to qualify, question and finally, after Abelard's condemnation in 1141, to drop the idea altogether. For him, the identification is no more than a reading of an ancient text, convenient but dispensable.

It was when classical texts provided him with scientific, rather than theological or philosophical ideas, that William took them most seriously and elaborated them for his own use. The account of creation which he gives in the *Philosophia* and the *Dragmaticon*, and also in the glosses to the *Timaeus*, shows how all things - not merely the heavens and earth, but also birds, fishes, animal and humans - came into being through the natural interaction of the four elements (fire, air, water and earth). Only the creation of the human soul required separate divine intervention. To potential critics who objected on religious grounds to such discussions, William argued that he was merely extending the account of creation in Genesis. The Bible says certain things were made: William is explaining *how* they were made. While remaining in the Catholic faith, he says, we should always look for a reason for things and only fall back on authority as a last resort. It is not enough to say 'God made it', because although God can act directly - as he does in miracles - he does not usually do so.

William of Ockham (*c*.1287-1347)

William of Ockham is a major figure in late medieval thought. Many of his ideas were actively - sometimes passionately - discussed in universities all across Europe from the 1320s up to the sixteenth century and even later. Against the background of the extraordinarily creative English intellectual milieu of the early fourteenth century, in which new varieties of logical, mathematical and physical speculation were being explored, Ockham stands out as the main initiator of late scholastic nominalism, a current of thought further exemplified - with important variants - by a host of authors after him, from Adam Wodeham, John Buridan and Albert of Saxony to the school of John Mair far into the sixteenth century.

As a Franciscan friar, Ockham taught theology and Aristotelian logic and physics from approximately 1317 to 1324, probably in Oxford and London. He managed to develop in this short period an original and impressive theological and philosophical system. However, his academic career was interrupted by a summons to the Papal Court at Avignon for theological scrutiny of his teachings. Once there, he became involved in the raging quarrel between Pope John XXII and the Minister General of the Franciscan Order, Michael of Cesena, over the poverty of the church. Ockham was eventually excommunicated in 1328. Having fled to Munich, where he put himself under the protection of the Emperor Ludwig of Bavaria, he fiercely continued the antipapal struggle, devoting the rest of his life to the writing of polemical and politically-oriented treatises.

Because he never was officially awarded the title of Doctor in Theology, Ockham has been traditionally known as the venerabilis inceptor*, the 'venerable beginner', a nickname which at the same time draws attention to the seminal character of his thought. As a tribute to the rigour and strength of his arguments, he has also been called the 'Invincible Doctor'.*

The core of his thought lies in his qualified approach to the old problem of universals, inherited by the Christian world from the Greeks through Porphyry and Boethius. Ockham's stand is that only individuals exist, generality being but a matter of signification. This is what we call his nominalism. In the mature version of his theory, species and genera are identified with certain mental qualities called concepts or intentions of the mind. Ontologically, these are individuals too, like everything else: each individual mind has its own individual concepts. Their peculiarity, for Ockham, lies in their representative function: a general concept naturally signifies *many different individuals. The concept 'horse', for instance, naturally signifies all singular horses and the concept 'white' all singular white things. They are not arbitrary or illusory for all that: specific and generic concepts, Ockham thought, are the results of purely natural processes safely grounded in the intuitive acquaintance of individual minds with real singular objects; and these concepts do cut the world at its joints. The upshot of Ockham's doctrine of universals is that it purports to validate science as objective knowledge of necessary connections, without postulating mysterious universal entities 'out there'.*

Thought, in this approach, is treated as a mental language. Not only is it composed of signs, but these mental signs, natural as they are, are also said to combine with each other into propositions, true or false, just as extra-mental linguistic signs do; and in so doing, to follow rules of construction very similar to those of spoken languages. Ockham thus endowed mental discourse with grammatical categories. However, his main innovation in this respect is that he also adapted and transposed to the fine-grained analysis of mental language a relatively new theoretical apparatus that had been emerging in Europe since the twelfth century: the theory of the 'properties of terms' - the most important part of the logica modernorum*, the 'logic of the moderns' - which was originally intended for the semantical analysis of spoken languages. Ockham, in effect (along with some of his contemporaries, such as Walter Burley) promoted this new brand of semantical analysis to the rank of philosophical method* par excellence*. In a wide variety of philosophical and theological discussions, he made sustained use of the technical notions of 'signification', 'connotation' and, above all, 'supposition' (or reference) and all their cognates. His distinctive contribution to physics, for example, consists mainly in semantical analyses of problematic terms such as 'void', 'space' or 'time', in order to show how, in the end, they refer to nothing but singular substances and qualities.*

Ockham's rejection of universals also had a theological aspect: universals, if they existed, would unduly limit God's omnipotence. On the other hand, he was convinced that pure philosophical reasoning suffices anyway for decisively refuting realism regarding universals, since all its variants turn out to be ultimately self-contradictory,

as he endeavoured to show by detailed criticism.

On the whole, Ockham traced a sharper dividing line than most Christian scholastics before him between theological speculation based on revealed premises and natural sciences in the Aristotelian sense, which are based on empirical evidence and self-evident principles. He wanted to maintain this clear-cut distinction in principle through all theoretical and practical knowledge, including ethics and political reasoning. In this last field, in particular, to which Ockham devoted thousands of pages in the last decades of his life, he strenuously defended the independence of secular power from ecclesiastical power, stressing whenever he could the autonomy of right reason in human affairs.

1 Life

William of Ockham was born around 1287, probably in the village of Ockham in Surrey, near London. Of his youth we know next to nothing, only that he joined the Franciscan Order (perhaps as a child), that he was ordained subdeacon in London on 27 February 1306 (an appointment for which he would normally have had to be at least eighteen), and that he was licensed to hear confessions on 19 June 1318 (for which he would have had to be at least 30). He must have studied Aristotelian philosophy - and especially logic - quite thoroughly before turning to theology in Oxford around 1310. Following the normal curriculum, he would then have spent the next seven years as a theology student and have lectured for two years (probably from 1317 to 1319) on Peter Lombard's *Sentences* (see Lombard, P.) The commentary that resulted is Ockham's first major work. It is a huge treatise in four books, the first of which was later revised by the author for publication and is known, for that reason, as the *Ordinatio*, while the other three, jointly known as the *Reportatio*, circulated merely in the form of a detailed, authorized set of students' notes.

This early, and strikingly original, work might already have raised misgivings in certain quarters at Oxford. Whether for that reason or some other, Ockham was not immediately granted the degree of master of theology, which would have entitled him to continue teaching in the field. He was sent instead to a Franciscan convent, possibly in London, to teach logic and physics, which he did from 1320 to 1324. This turned out to be a very productive period, during which he wrote his commentaries on Porphyry's *Isagoge*, Aristotle's *Categories*, *On Interpretation* and *Sophistical Refutations*, and at least part of his commentary on Aristotle's *Physics*. He also revised his *Ordinatio*, engaged in public disputations on various matters theological and philosophical, and wrote a few more treatises on especially delicate questions such as transsubstantiation and God's foreknowledge. In the same years he may also have begun (or even completed, according to some) his great *Summa logicae (Summa of Logic)*; originally intended for beginners, it eventually became one of the major reference books for the new nominalistic semantics and logic which was to be so influential in the fourteenth and fifteenth centuries.

In the summer of 1324, Ockham left England for Avignon. Most scholars think he was summoned to the papal court there by Pope John XXII for investigation of his teachings. In the previous year a Provincial Franciscan Chapter held in Cambridge had already publicly raised questions about some of his philosophical theses that could be deemed theologically dangerous. In 1325, the Pope established an advisory commission of six renowned theologians to examine fifty-one articles extracted from Ockham's commentary on the *Sentences*. The group included the French Dominican Durandus of St Pourçain, otherwise known for his nominalistic sympathies, and John Lutterell, the ex-Chancellor of Oxford and one of Ockham's fiercest opponents. In 1326 the commission gave a preliminary report, which, while identifying many of Ockham's opinions as erroneous, did not condemn any as clearly heretical. Apparently this did not satisfy the Pope, and a second report was prepared, much more along Lutterell's lines. Ockham became officially suspected of heresy, especially with regard to his theory of moral merits, which was accused of Pelagianism (see Pelagianism), and in 1327 Pope John XXII launched a formal inquisitorial process against him.

This process was never brought to a conclusion. However, Ockham in the meantime had got involved in other sorts of troubles. It is probable that during his first years at the Franciscan convent in Avignon, he continued to work on some of his philosophical or theological treatises, such as the *Summa logicae*, the *Quodlibeta septem (Seven Quodlibetal Questions)* and the *Expositio in libros Physicorum Aristotelis (Commentary on Aristotle's Physics)*. Towards the end of 1327 the Franciscan Minister General, Michael of Cesena, who had himself been recently summoned to Avignon by the Pope, ordered Ockham to study John XXII's bulls of 1322-4 on whether Christ and the Apostles had owned anything and on the poverty of the Franciscan Order in particular. The question was

delicate. The papal court was by then scandalously opulent, and John XXII was very much aware of the challenge to it by the advocacy of poverty that had been spreading in many Franciscan quarters in the previous decades. His series of bulls on the subject had been intended to put a stop to this movement. Comparing these with the Gospels and the writings of previous popes, Ockham boldly concluded that John XXII was himself heretical. Matters eventually got worse between Michael of Cesena and the Pope, and on the evening of 26 May 1328 five Franciscans, including Michael and William, fled from Avignon, fearing for their lives. Having narrowly escaped the Pope's soldiers, they reached Pisa by boat and joined another enemy of John XXII, the Emperor Ludwig of Bavaria. All five were immediately excommunicated.

From 1330 on, Ockham stayed at the Franciscan convent in Munich under the protection of Ludwig of Bavaria and devoted himself to the writing of political treatises. At first, the goal of Michael of Cesena's supporters was to convince the Christian community that John XXII ought to be deposed. Such was the context for Ockham's *Opus nonaginta dierum (Work of Ninety Days)*, written in three months in 1332 or 1333, and for the first part of his important unfinished dialogue on the distribution of powers within and outside the church, known simply as the *Dialogus*. In December 1334, John XXII died. Political discussions were opened between Ludwig of Bavaria and the new Pope, Benedict XII, during which Ockham's literary activity was brought to a halt. However, no agreement was reached, and from 1337 to 1342 he produced an impressive number of new writings in which he defended more and more explicitly the independence of the imperial and royal powers from those of the Pope. Especially worth mentioning are the *Tractatus contra Benedictum (Treatise Against Benedict)*, the *Octo quaestiones de potestate papae (Eight Questions on the Power of the Pope)* and treatises 1 and 2 (the only ones extant) of *Dialogus* III. After another hiatus at the time of Clement VI's accession to the papal throne, Ockham finally synthetised his political thought in the treatise *De Imperatorum et Pontificum potestate (On the Power of Emperors and Popes)* in 1346 or 1347. He died in April 1347, a few months before Ludwig of Bavaria. Contrary to an old legend, he had taken no steps toward submitting to the Avignon church.

2 Ontology: antirealism

The core of Ockham's philosophical system lies in the idea that only individual beings exist and that universals are nothing but signs, spoken, written or mental. This is what has been called his *nominalism*, a label that came to be associated with his thought towards the end of the fourteenth century (see Nominalism).

The theoretical problem it was intended to solve was provided by Porphyry's old questions about universals (see Porphyry): do species (such as 'horse') and genera (such as 'animal') exist by themselves outside the mind or not? Are they corporeal or incorporeal? And are they located in the individual beings or do they exist apart from them? By Ockham's time, Platonism, identified as the position according to which universals do exist outside the mind as incorporeal beings over and above the individuals that participate in them, had fallen into disrepute (see Platonism, medieval). Aristotle was credited with having definitively refuted it. Most philosophers, then, would follow Thomas Aquinas or John Duns Scotus in adopting some form or other of what we today call 'moderate realism', the thesis according to which universals exist outside the mind but only within the individuals that exemplify them. But this, in the eyes of Ockham, was 'the worst error in philosophy'; and his defence of his own ontology - which he always presented as orthodox Aristotelianism - consisted largely in a detailed, ruthless criticism of the different variants of moderate realism (see Aristotelianism, medieval).

For one thing, he deemed them all incompatible with God's omnipotence. If the universal 'horse' was a common part of each individual horse, then God could not completely destroy any single horse - Bucephalus, for example - without destroying all the others; for in order to destroy the universal 'horse' that was part of Bucephalus, God would have to destroy all the other horses as well. This overtly theological argument reveals one of Ockham's deepest philosophical intuitions: everything that exists, he insisted, should be logically independent of any other thing. This ontological atomism is what he frequently expresses by means of thought experiments involving God's omnipotence. Since God is credited with the power to do anything which is not self-contradictory - a fundamental theological principle, according to Ockham - the realm of what he can do corresponds to the whole array of logical possibilities, and he should, in particular, be able to destroy any single contingent being while keeping any of the others in existence.

However, Ockham's main accusation against the varieties of moderate realism he identified among his contemporaries is that in one way or another they all fall short of internal logical consistency. His chief weapon in

ontological disputes was the principle of non-contradiction. The best example of this line of attack lies in his famous critique of Duns Scotus' 'formal distinction'. Scotus, also a Franciscan, whose work Ockham deeply respected and often discussed at great length, had held that the universal natures such as equinity or animality did have some sort of existence outside the mind, but that they were not *in reality* distinct from the individuals that exemplified them. They were merely, Scotus contended, *formally* distinct from them. By this distinction he meant that while they could not exist in reality apart from their individual exemplifications - even by God's omnipotence - there nevertheless was a 'foundation in the thing' for thinking of them as separate. Scotus, like Ockham after him, was dissatisfied with any version of moderate realism that posited the universal nature as being both internal to the individual thing and really distinct from it, because this would entail that the individual thing and the universal nature should logically be able to exist apart from one another, which leads to absurdities. On the other hand, Scotus thought that the validity of the conceptual distinction between the universal and the individual did require that they should not be wholly identical with one another: hence his idea of a formal distinction within real identity.

According to Ockham, this leads directly to contradiction. If the universal nature and the individual thing are really identical to one another, then whatever is true of one of them should also be true of the other, and thus it will be true of the same thing that it is both universal and not universal, individual and not individual. Conversely, if incompatible predicates such as universality and individuality are attributed respectively to the common nature and the individual thing, then this in itself suffices to show that they are distinct from one another *in reality*, for this is precisely the paradigmatic way of proving that two things are really distinct from one another. Scotus' formal distinction thus collapses into the real distinction he wanted to reject in the first place. It is easy to see that this argument, like many others Ockham adduces in similar contexts (against Aquinas, for example), makes a crucial use of what we nowadays call the principle of the indiscernibility of identicals: if *a* and *b* are identical to one another, then whatever is true of *a* is true of *b*; conversely, if something is true of *a* which is not true of *b*, then *a* and *b* are really distinct from one another.

To avoid an old misunderstanding, it must be stressed that Ockham's critique of the ontology of universals does not explicitly rely on the methodological principle of economy that Sir William Hamilton, in the nineteenth century, labelled 'Ockham's razor': entities are not to be multiplied without necessity. It is true that Ockham's thought consistently shows a strong drive towards ontological economy and that he did on many occasions use the razor (which he himself formulated either as 'a plurality should never be posited without necessity' or as 'it is pointless to do with more what can be done with fewer'). However, this principle was commonly accepted before him, even by realist philosophers. It was thought of - by Ockham as well as by others - as a mere methodological rule which, taken by itself, yielded only 'probable' conclusions. By contrast, the refutation of the external reality of universals was considered by Ockham as absolutely conclusive since it rested on the principle of non-contradiction.

3 Ontology: substance, quality, form, matter

Although Ockham's nominalism posits only individual things in the external world, it nevertheless admits of ontological differences among them. First of all, he accepted (for a time) a fundamental difference of status between extramental and mental existence. While universals were refused the former, they were granted the latter. They were thought of, in the first version of Ockham's *Ordinatio*, as enjoying a special sort of intentional existence in the mind. This was the existence appropriate to a *fictum*, a mind-made intelligible object which existed only while consciously produced by the mind as an abstract correlate for acts of intellection, and which, for the duration of its existence, could serve as a natural sign representing certain individual beings. Admittedly, there was no room for this sort of existence within the framework of Aristotle's ten categories, but Ockham at first explained away this lacuna by restricting Aristotle's taxonomy to a limited theory of predicates for extramental entities. Later on, however - probably in the early 1320s, under the incisive criticism of his confrère Walter Chatton - Ockham realized that he could achieve an important ontological economy by letting the act of intellection itself play the role of the natural sign. Since internal acts, interpreted as actualized mental potentialities (*actus*), were commonly classified as qualities of the mind, no special ontological category was needed any longer for intramental existence. The intentional *fictum* could simply be dropped as soon as one recognized that intellectual acts themselves can serve as semantic contents without any need for internal correlates after all. This is a salient instance of Ockham's actually using the razor principle: after a period of hesitation, he finally favoured the *actus*

theory over the *fictum* theory as more probable because it could do with less what the other did with more.

However, even with this simplification, ontology was not utterly stripped of categorial plurality. For one thing, Ockham always maintained a fundamental distinction between substances and qualities. Although he interpreted Aristotle's theory of the ten categories as a classification of signs rather than things, he would nevertheless acknowledge, corresponding to it, a basic duality amongst individual entities themselves. Substances, whether corporeal or spiritual, were thought of along the Aristotelian line as autonomous beings, while qualities were held to depend upon them for their own existence. Qualities, Ockham would say, 'inhere' in the individual substance which displays them. They are not essential parts of it, however, and any one of them can be removed (by natural causes or by God's omnipotence) without the substance losing its identity. Each substance, on the other hand, has many qualities, simultaneously and successively, and each one has its own: the whiteness of Bucephalus is a particular thing, numerically distinct from Bucephalus itself and from all the whitenesses of any other beings in the world as well, however similar they might be. Ockham endorses particularism with respect to qualities.

Moreover, this nominalistic ontology is further complicated by the incorporation of Aristotelian hylomorphism, the theory of matter and form. Each singular composite corporeal substance is endowed with a variety of internal parts without which it would not be itself: a certain parcel of prime matter on the one hand, and one or more substantial forms on the other hand. Each human being, for example, is a compound of a determinate piece of matter and a number of substantial forms, such as a nutritive form, a sensory form and an intellectual form. Although these *partes essentiales* are naturally incapable of existing by themselves outside the hylomorphic compound, they are nevertheless counted by Ockham as real, and therefore singular, beings. Matter is thus granted a certain actuality of its own (in opposition to Aquinas). Forms, on the other hand, are stripped of intrinsic generality, each substance having its own.

Ockham, in summary, admits of four basic sorts of singular beings: substances, qualities, substantial forms and pieces of matter. Together they make up a still comparatively simple ontological system, of which singular substances constitute the core, qualities being attached to them as external properties, and forms and matter incorporated as internal parts.

What struck Ockham's contemporaries in this picture - and many commentators after them - was that it left out not only universals, but relations and quantities as well. These last exclusions, in fact, were a major source of Ockham's early troubles with religious authorities. The Catholic church was at the time imposing severe pressure on philosophical theories, for fear that philosophers might rule out any of its doctrines as impossible. The doctrines of the Trinity, the Incarnation and the Eucharist in particular, were commonly considered as having important implications for theories about relational connections (such as parenthood or ownership) and quantitative dimensions (such as weight, height or length). Ockham held that neither those connections nor those dimensions had any distinct existence of their own, and this aroused suspicion. However, Ockham had not meant to say that sentences making relational or quantitative claims were neither true nor false, or arbitrarily so. Most of them, he thought, are indeed true or false independently of the human mind: it is not the intellect, for example, that brings it about that Plato is taller or heavier than Socrates. What makes such sentences true or false, Ockham strenuously tried to show, is nothing but substances and qualities themselves. What characterizes a relational or a quantitative sentence, he would typically say, is not the sort of things needed to make it true, but its terms' modes of signifying. This last point he developed indefatigably and argued for in great detail. To the semantics of quantitative language, in particular he devoted many lengthy passages in his major works, as well as the bulk of two special treatises on the Eucharist, *De corpore Christi (On the Body of Christ)* and *De quantitate (On Quantity)*, which were obviously written as defences against theological attacks.

4 Epistemology: intuitive and abstractive cognition

Apart from pointing out the inconsistency and imprecision of his opponents, what Ockham had to do in order to accredit his simplified ontology was also to explain as clearly as possible how it fitted with Aristotelian science and with Christian doctrine. For this he had especially to account for the adequacy of knowledge in general. It was a respected Aristotelian adage that science had essentially to do with universals. How could it be salvaged if there are no such universals in reality? Ockham answered the challenge by providing a detailed theory of how mental universals are produced, a theory that was meant as the basis for any validation of conceptual knowledge.

The epistemological process, in this picture, always starts as a direct encounter between singular beings. When a knowing mind equipped with both sensory and intellective substantial forms is in the presence of a perceptible singular object such as a table or a horse, a causal chain naturally ensues, according to Ockham. First, there occurs an apprehension, or *intuition*, within the sensitive part of the mind. This in turn, together with the object itself, causes certain actual states, or *actus*, in the intellectual part, states which Ockham labels ‘intellectual intuitions’. These are characterized by the fact that they naturally elicit within the intellect true contingent beliefs about the world, especially judgments regarding existence or non-existence. If Socrates has the right relation to Bucephalus (perceiving it from the right distance, awake, sane and so on), there naturally takes place within Socrates a simple intellectual act, his ‘intuitive cognition’ of Bucephalus, which in turn causes his judgments that Bucephalus exists, is white, is standing there and so on.

Such judgments, of course, even though they are singular, require the availability of certain general concepts such as those of whiteness and existence. These, in Ockham’s view, are also brought about by the same concrete intuitions through an equally natural course. Every time Socrates forms an intuitive act caused by a certain individual in the world, there occur within Socrates’ mind other derivative simple intellectual acts, called *abstractive* cognitions. These new acts in themselves will not induce empirical judgments of existence; and for that reason they are said to ‘abstract’ from existence and non-existence. However, in virtue of a certain isomorphism (*similitudo*) they have with the original external thing, they may be used by the mind to represent or stand for this very same thing in its absence, and for any others as well that resemble it sufficiently for the same isomorphism to hold. General signs are thus naturally generated, either as mind-made objects of abstractive acts (according to the *fictum* theory) or as abstractive acts themselves (according to the *actus* theory). In either case, the result is what Ockham calls the mind’s concepts (*conceptus* or *intentiones*). General concepts, for him, are always causally derivative: ‘every naturally acquired abstractive cognition of a thing presupposes an intuitive cognition of the same thing’ (*Ordinatio*).

Intellectual intuitions and abstractive concepts, then, are simple mental terms or signs, each naturally representing one or more singular beings in the world. Once produced, these simple terms can be combined with each other, by natural causes or by the will of their possessors, to form cognitive complexes, such as mental propositions. A mental proposition is a structured sequence of mental terms that is either true or false with respect to the singular beings that are referred to by its terms. Such a propositional complex is formed by an intellect’s composite act of apprehension (*actus apprehensivus*). In the *fictum* theory, Ockham saw the mental proposition as the intentional correlate of this complex apprehensive act, but later he simply identified the two in the *actus* theory. Once the mind apprehends a proposition, it can go further and commit itself with respect to its truth or falsity; this is the act of assent, the judgment (*actus judicativus*). Mental propositions, finally, can be compounded with each other in chains of reasonings, theoretical or practical.

The detailed theory of exactly which structural features and relations with the world render a mental proposition true or false was part of logic for Ockham (see §7 below). Supposing that this semantical part of the programme can be achieved, the general picture we have of knowledge in Ockham’s final theory is that of a natural causal process, involving, apart from external objects themselves, only real qualities of the mind, and leading in stages from intuitive encounters with external singular beings to judgments and inferences involving complex propositional contents, each basic signifying unit in the process being a singular act of a singular mind. There is no longer any such thing as *the* concept ‘horse’, for example; only token concepts exist. Every mind forms its own single, momentary intellectual acts, which owe their generality, if any, to their signification rather than to a special mode of existence: ‘Nothing is universal save by signification’ (*Summa logicae* I, 14).

Such mental tokens normally will not subsist very long, but they leave traces when they disappear. We keep intellectual memories of them. Abstractive acts, Ockham contends, causally generate within the mind certain corresponding dispositions (*habitus*) to form similar acts in the future, and these cognitive dispositions are themselves identified with real qualities of the mind. Thus a general concept comes to be available to a particular mind for future use. When Socrates met Bucephalus, there naturally occurred within Socrates an intellectual intuitive cognition of Bucephalus; and then, as a causal result of this, abstractive cognitions were also produced, which turned out to be capable of simultaneously representing all beings in the world that are sufficiently similar to Bucephalus. In this way Socrates acquires the concept of a horse, the concept of a white thing and so on. Once formed, these general concepts elicit in turn mental dispositions within Socrates to produce replicas of them under

appropriate circumstances, new mental tokens representing all horses or all white things, just as the original acts did.

Accordingly, sciences - organized bodies of knowledge - are described by Ockham as 'collections of intellectual *habitus*' in the mind of particular knowers. To say of someone that they have a certain science - that of grammar, for example - is to say that they have internalized, as real qualities of their mind, a certain collection of intellectual dispositions which enable them to form general propositions of grammar when required and which adequately incline them to assent with certainty to those which are true: sciences are ultimately made up of apprehensive and judicative psychological dispositions. Ockham has often been taken to task for having taught that the objects of a science, like the objects of all knowledge or belief, are mental propositions rather than things themselves; but by this he only meant that mental propositions - corresponding to complex apprehensive acts - are precisely what knowers are inclined to assent to by the sciences they have internalized. The contents of knowledge are thus seen as sequences of mental propositions, of which certain terms naturally signify certain singular beings in the world. Thought is mental discourse.

5 Epistemology: direct realism

Ockhamism has often been suspected of leading to radical scepticism in epistemology. If general concepts represent nothing but independent individual things, how can such groupings fail to be arbitrary or misleading? But radical scepticism was, in fact, very far from Ockham's intentions and spirit, and his theory of universals and knowledge has been more accurately characterized by the best commentators as 'realistic conceptualism' (Boehner 1958) or 'direct realism' (Adams 1987) (see Epistemology, history of).

For one thing, as was seen in the previous section, the process of concept formation is completely natural. It is the same in every human being and leaves no room for idiosyncratic vagaries. Secondly - and most importantly - this naturally acquired stock of concepts does cut the world at its joints, according to Ockham. Species and genera, of course, are denied any outside reality as distinct beings, but Ockham readily grants that whether an individual thing is or is not of the same species or of the same genus as another is not for the human mind to decide. The conditions of being in the same genus or of the same species are not subjective or arbitrary. They are determined, on the contrary, by what the individual things are in themselves and how they in fact stand to each other. Whether something resembles Bucephalus enough to be naturally represented by the same general concepts does not, Ockham insists, depend upon the human mental apparatus at all. It simply is a rock-bottom fact of the universe. Concept formation, being a natural process, derivatively mirrors the natural distribution of causal powers among individual things, which powers depend in turn on real singular essences and qualities. In this lies the adequacy of abstractive cognition.

Different kinds of accurate, simple, general concepts are thus formed on the basis of direct experience, according to this theory. First, there are more or less general substantial concepts, such as 'horse' or 'animal', which are identified with species and genera and which are taken to represent in the mind certain groups of individual substances essentially similar to each other independently of their qualities. Second, there are concepts such as 'whiteness' or 'colour', which represent immediately perceptible singular qualities of substances but not substances themselves. Third, there is another sort of qualitative concepts, such as 'white' or 'coloured', which represent substances - white things or coloured things in the chosen examples - insofar as they possess certain perceptible qualities. Finally, there are some elementary relational concepts such as 'darker' or 'taller', which represent individual beings - substances or qualities - insofar as they are related to some others in certain perceptible ways. The first two groups are called 'absolute concepts', while the last two are classified among 'connotative concepts' (see §6), but all of these are simple mental terms naturally generated as causal results of empirical encounters with singular objects, without any combinatorial activity from the intellect. Together, they are held to provide an adequate basis for knowledge.

Is this empiricism? It would appear so, insofar as it holds that the formation of simple representative concepts in human minds is always triggered by direct singular experiences (of external objects or of mental states themselves). However, it must be stressed that the cognitive process described by the theory presupposes a very strong innate apparatus of rational capacities. A well-formed basic species-concept such as 'horse', for example, is automatically generated, according to Ockham, as the result of a single encounter with a horse. More general genus-concepts such as 'animal' are formed, in turn, as the results of a minimal number of encounters with

individuals of different species. Moreover, certain true contingent beliefs, such as ‘a horse exists’ or ‘this horse is larger than this dog’ are naturally triggered in the mind, as has been seen, as the results of causal processes which also involve highly determinate mental machinery. Certain universal truths are even supposed to be immediately known as such by the mind once the relevant concepts are made available to it, for example, that all horses are animals. The mind, according to Ockham, is equipped from the start with a rich apparatus of cognitive capacities which enable it, under the right circumstances, to reach true scientific knowledge.

One independent reason for linking Ockhamism with scepticism has sometimes been found in its acceptance of the possibility of an intuitive or pseudo-intuitive cognition of nonexistent beings (see Scepticism). However, two different theses must be distinguished in this respect, and neither of them, in Ockham’s view, leads to radical scepticism. First, Ockham did admit the theoretical possibility of an intuitive cognition of nonexistent beings, realizable only, he thought, by the supernatural intervention of God. Since an intuitive act is a real quality of the mind, he reasoned, it is itself a singular being distinct from its own external object; and hence, it is not self-contradictory that it should exist without the object. If this is not self-contradictory, then God can induce in a prophet’s mind, for example, a certain singular cognition of a presently nonexistent being, in virtue of which the prophet would know that this particular being - a future one, or even a merely possible one - does not presently exist, but that it will exist in the future or that it would exist under appropriate circumstances. This singular cognition would then be an adequate intuitive cognition since it would cause within the prophet’s mind true existential judgments about the thing in question. Accordingly, there is no hold for scepticism here: such a supernaturally induced intuition, although abnormal, would not be misleading.

The second possibility seems more disturbing. Ockham admits, since this is not self-contradictory either, that God could directly cause in any human being the *false* belief that there is a horse in front of them while in fact there is none. Strictly speaking, this would not be an intuitive cognition (it would not cause a true judgment of existence or non-existence), but it could certainly be an undetectable source of error. Such a possibility, however, does not belong to the range of natural processes; and, although it cannot be ruled out by the theory, it can in practice be disregarded by the epistemologist who wishes to assess the scope of natural knowledge. In the normal course of things, intuitive cognition is a totally reliable starting point for science.

6 Logic and philosophy of language: levels of discourse, connotation, intentions

Once concepts are available as natural signs, mental propositions can be assembled. Their truth and falsity will depend upon the semantical properties of their component terms and their syntactical arrangements. Thought is seen as an internal discourse with a compositional structure very similar to that of spoken sentences. Ockham took the ancient idea of mental discourse (found in Boethius, for example) more seriously than any other philosopher before him, and his logic systematically exploits, for the analysis of mental propositions and inferences, the theory of the properties of terms (*proprietates terminorum*) to which he had been introduced as a student. This theory was an original medieval contribution, which had been progressively developed since the twelfth century by a host of logicians such as Peter of Spain and William of Sherwood, for the analysis of spoken sentences. Ockham adapted it to his nominalistic ontology on the one hand, and enlisted its rich apparatus of concepts and distinctions on the other hand - the theory of *suppositio* in particular - in the service of a fine-grained understanding of mental computation. This is to a large extent what his logic is about (see Logic, medieval).

At the very outset of *Summa logicae*, Ockham states that there are three levels of propositions: spoken, written and mental. Those of the first two groups, he says, are composed of publicly perceptible signs, visible or audible; but mental propositions are sequences of concepts - or intentions of the mind - existing only in the privacy of the intellect. Each proposition is composed of terms, and the basic semantical property in this picture is the signification (*significatio*) of the component terms. The signification of a concept is natural, as has been seen, and that of the other two sorts of terms is conventionally derived from it: spoken terms are conventionally subordinated to concepts, and written terms are conventionally subordinated to spoken ones. A spoken or written term inherits the signification of the previously existing sign to which it is subordinated. When the Latin spoken word ‘*equus*’, for example, is conventionally subordinated to the mental concept ‘horse’, it thereby acquires the signification that belonged to that concept naturally; and the very same signification is afterwards transmitted in the same way to the corresponding written term. Ockham, then, refuses to say - as did Boethius and Aquinas, among others - that a spoken word signifies the underlying concept. It will instead be said to signify conventionally the individual things

themselves that the concept was a natural sign of in the first place: real singular horses in the case of the spoken words ‘horse’, ‘*cheval*’ or ‘*equus*’, for example. The same will hold, *mutatis mutandis*, for the corresponding written words.

At each of the three levels, many distinctions are to be drawn among terms with respect to their signification. First, categorematic terms are distinguished from syncategorematic ones by the fact that they do have a signification of their own before being combined with others into propositions. Proper names such as ‘Socrates’ and common nouns or adjectives such as ‘horse’ or ‘white’ are salient examples of categorematic terms. *Syncategoremata*, on the contrary, are particles such as prepositions, logical connectives and quantifiers, which do not when taken alone direct the mind towards particular individual beings in the world. Their semantical roles are ancillary: they do not signify anything by themselves but, when combined with categorematic terms, they can affect the modes of reference of those terms and determine the truth-conditions of propositions.

Another important distinction found in mental language as well as in spoken and written discourse, according to Ockham, is between absolute and connotative terms. The former correspond to what we today call natural kind terms, such as ‘horse’ or ‘animal’. These are characterized by the fact that they simultaneously and equally signify all the individuals they are true of, and nothing else: ‘horse’ signifies all horses and nothing but horses. Each connotative term, on the other hand, has at least two different groups of significates: its primary significates are the individuals the term is true of; and its secondary significates are individuals also called to mind by the term, but in an ‘oblique’ way. ‘White’, for example, is a salient case of a connotative term: it primarily signifies all white things and secondarily signifies - or connotes - their whitenesses; although it cannot be said that whitenesses are white, they are nevertheless obliquely called to mind by the term ‘white’. All relational terms, Ockham insists, are connotative: ‘owner’ primarily signifies all owners and connotes their possessions, ‘father’ primarily signifies the fathers and connotes their children, and so on. This idea of connotation thus turns out to be a crucial device for the simplification of ontology. All significates, whether primary or secondary, are singular substances or qualities, and nothing else. Relations, in particular, are no longer needed among real beings. The relevant complexity, here, is located in the semantical structure of certain terms rather than in the ontology.

Finally, some terms signify nonlinguistic things, while others signify signs. When restricted to mental terms, this idea is cashed out, in Ockham’s vocabulary, as a distinction between ‘first and second intentions’. First intentions are mental terms, the significates of which are external beings. Aristotle’s theory of the ten categories is precisely interpreted in this framework as a classification of first intentions according to their modes of signification: the category of relation, for example, is identified with the group of relational first intentions such as ‘owner’ or ‘mother’, the category of quality with that of qualitative first intentions such as ‘white’ or ‘whiteness’, and so on. Second intentions, on the other hand, are concepts signifying concepts. Philosophically, in Ockham’s eyes, the most interesting instances of these are the mental terms ‘species’ and ‘genus’ themselves. ‘Species’ is seen as a metalinguistic concept signifying certain general terms such as ‘horse’ or ‘dog’, while ‘genus’ amounts to approximately the same except that it signifies terms even more general, such as ‘animal’ or ‘flower’. This is exactly what realism about universals crucially misses: it fails to see that concepts referring *to* universals are fundamentally metalinguistic (see Language, medieval theories of).

7 Logic and philosophy of language: supposition and inference

Signification, then, in Ockham’s logic, is a pre-propositional property of categorematic terms taken in themselves. When such a term, whether spoken, written or mental, is inserted into a proposition as subject or predicate, it is said to acquire a new semantical property called *supposition*, which is derivative with respect to its signification but which, contrary to signification, can vary from one proposition to another according to contextual factors. Supposition, in modern terms, is the referential function fulfilled by the term in a given propositional context: for a term to ‘supposit for’ certain things, Ockham says, is just for it to stand for these things in a given proposition.

Normally a subject or predicate term supposits for its primary significates. It is then said to be taken in personal supposition (*suppositio personalis*): in ‘some horses are white’, for example, the subject term ‘horse’ personally supposits for - or refers to - all horses, whether white or not, while the predicate term ‘white’ personally supposits for all white things (but not for whitenesses, which are its secondary significates). Special cases can occur, however: in a sentence such as ‘horse is a five-letter word’, the subject term ‘horse’ does not stand for its primary significates - real horses - but for written tokens of the English word ‘horse’. When a term thus supposits for

spoken or written tokens of itself, it is said to be taken in material supposition (*suppositio materialis*). When it stands for tokens of the corresponding mental sign, such as ‘horse’ in ‘horse is a concept’, it is said to be taken in simple supposition (*suppositio simplex*). This last case is especially important in Ockham’s discussion of the problem of universals, since the subject terms of sentences such as ‘horse is a species’ or ‘animal is a genus’ are typically considered by him as being taken in simple supposition, and interpreted accordingly as referring in a special way to mental tokens rather than to mysterious external entities such as equinity or animality.

Which individual beings a term refers to in a certain propositional context is thus determined in the first place by the signification of the term and by whether it is taken in personal, simple or material supposition. However, this is still incomplete. It is also determined, Ockham insists, by the tense and the modality of the main verb in the proposition, according to precise rules. A present-tense verb, in particular, is said to restrict both the subject and the predicate of the proposition to supposit for individual beings which exist at the time of utterance. A past-tense verb restricts the predicate to supposit for past individuals, but allows the subject to supposit both for past individuals and for individuals existing at the time of utterance, and so on.

In this way, propositions are linked to reality. Discourse, whether spoken, written or mental, refers to nothing but singular entities, some of which are themselves significant tokens, and it does so through the referential functions of the terms in specific contexts. Propositions considered as complex semantical units do not, according to this view, signify special entities over and above the *supposita* of their terms. Their peculiarity instead is to have truth-conditions, a detailed theory of which Ockham gives in the second part of his *Summa logicae*. For elementary statements of the form ‘subject + copula + predicate’, these truth-conditions are entirely formulated in terms of relations between the supposition of the subject-term and that of the predicate. For the truth of a universal affirmative proposition, for example, it is both necessary and sufficient that the predicate supposits for all the individuals the subject supposits for. Similarly, the truth of a universal negative proposition requires that the predicate have no common *supposita* with the subject, and so on. The theory gets more complicated when it reaches modal propositions, non-elementary propositions (such as conjunctions, disjunctions or conditionals) or other difficult cases such as propositions involving special verbs like ‘cease’ or ‘begin’, which fascinated logicians in the fourteenth century. However, the basis is always provided by the referential link established through supposition between the terms in the proposition and the singular beings out there in the world.

The same is true generally of Ockham’s theory of inferences developed in the very long third part of *Summa logicae*. This is not formal logic in the modern sense. The validity of inferences is always made to rest in the last analysis upon the referential properties of the component terms. Syllogisms, notably, are described as special arrangements of terms, and their validity is said to depend on the connections between the purported suppositions of the major, the minor and the middle terms. The whole syllogistic theory, in Ockham’s view, ultimately rests, directly or indirectly, on only two relevant connections between terms: the *dici de omni* (being said of all) and the *dici de nullo* (being said of none). The former holds when a certain term *A* supposits for everything another term *B* supposits for, and the latter when *A* supposits for none of the *supposita* of *B*. ‘All horses are mammals, all mammals are animals, therefore all horses are animals’, for example, is based on the transitivity of the *dici de omni*. ‘No stone is an animal, all horses are animals, therefore no horse is a stone’ is based on an interplay between the *dici de omni* and the *dici de nullo*. All other syllogistic figures are reduced in one way or another to these two connections. In the same vein, nonsyllogistic inferences - which had come to be a major new field of interest in medieval logic under the heading of *consequentiae* - are also systematically analysed by Ockham as depending upon interconnections between the suppositions of terms. This is how he is led to accept the soundness of such direct inferences as ‘all animals run, therefore all horses run’ or ‘no material body exists, therefore no white thing exists’, the key to which lies not in the formal structure, but in the semantical relations between terms, and ultimately on their reference to singular beings (see Language, medieval theories of; Logic, medieval).

8 Physics

The objects of science for Ockham, as was seen in §4, were universal mental propositions. This controversial thesis, however, did not lead him anywhere near idealism or scepticism, precisely because the supposition of terms was called upon to secure the required links between such mental propositions and real external individual beings. Natural science in particular was recognized as adequate general knowledge of sensible substances. Ockham in fact devoted several treatises to it, the most important of which are his unfinished *Expositio in libros Physicorum*

Aristotelis, his *Summa philosophiae naturalis (Synopsis of Natural Philosophy)* and his *Quaestiones in libros Physicorum Aristotelis (Questions on the Physics of Aristotle)*. Taken together, these three works occupy more than 2,000 pages in the Franciscan Institute edition and contain some of Ockham's most intriguing ideas.

The main goal of natural philosophy, as Ockham sees it, is to provide a theory of the general principles of change among sensible things. Following Aristotle, Ockham acknowledges different types of change in nature: generation and corruption of substances, intensification and diminution of qualities, rarefaction and condensation of matter and, finally, local motion. About each one of these he has detailed - and often provocative - positions to defend. However, in the last analysis all change is accounted for in his system on the sole basis of the four kinds of beings admitted by his ontology: substances, qualities, substantial forms and prime matter. Much of his natural philosophy is accordingly devoted to showing that space, void, time, motion and the like are not distinct, absolute things. Prime matter in particular is considered as being actually extended by itself, and its spatial dimensions are not - as in Aquinas and many other medieval authors - given the status of special quantitative forms enjoying an existence of their own.

The core of the method in this peculiar variety of physics is neither empirical nor mathematical but semantical, the point being to show that general sentences which appear to be about space, void, time or motion are in fact about substances, qualities, forms and pieces of matter. Thus reinterpreted, such sentences can very well convey truths, even necessary truths, about physical reality. The crucial device for this type of reductive analysis is the idea that a single word in spoken or written language, such as 'motion' or 'time', is often an abbreviation for a complex mental expression including not only absolute categorematic terms, but also conjunctions, adverbs, verbs and, above all, connotative terms. Moreover, these abbreviative words are often to be interpreted contextually - for example, the analyst should not systematically try to replace the relevant word by one and the same definition in all its occurrences, but should instead try to reformulate, on the basis of a few rules of thumb, the whole sentences in which the problematic word occurs.

An abstract noun such as 'change' (*mutatio*), for example, does not designate a special entity of its own. Rather, its uses are derivative with respect to those of the corresponding verb 'to change' (*mutare*). The meaning of the verb in such a case provides the key for the interpretation of the various sentences in which the derivative noun occurs. The verb 'to change' in effect normally applies to something (for example, a substance) acquiring something which it did not have before (for example, a new form or a new quality) or entering into relations with new things (for example, new substances). This is what should be kept in mind when considering spoken or written sentences involving the derivative noun, such as 'every change is by an agent' (which is to be interpreted as 'everything that changes is changed by an agent') or 'change moves from the prior to the posterior' (which means that 'when something changes, it moves from a prior state to a posterior state'). The term 'motion', in the same vein, normally supposits for the things which are moved, but it may also, if the context favours it, supposit for the things that cause the others to move; or it may even in special cases receive a metalinguistic interpretation and supposit for linguistic or conceptual units such as the verb 'to move'. The word 'time', to take a last example, does not signify any special extramental entity either, but supposits, in the sentences in which it occurs, for the very same things the word 'motion' would supposit for in similar contexts, and connotes in addition a certain numbering activity of the human soul.

Sentences involving such words, then, can be 'saved' without enriching the ontology, and when they are so reinterpreted, it can be admitted that their truth or falsity is neither illusory nor subjective. Nominalism here does not preclude the objectivity, the mind-independence, or even the necessity of physical phenomena. Ockham in particular is no precursor of Hume in being suspicious about natural causality. Efficient causality in his view is a natural necessary connection holding between singular causes and singular effects in virtue of their respective intrinsic natures; and it can be safely ascertained as such in appropriate circumstances. Ockham readily grants a causal version of the principle of the uniformity of Nature: 'causes of the same kind have effects of the same kind' (*Ordinatio*, prologue, q. 1). The fact that a certain individual *A* is, in virtue of its intrinsic substantial forms, of the same species as another individual *B* necessarily implies a strong similarity between *A* and *B* with respect to their causal powers. This is true to such an extent that a single observation, in appropriate circumstances, suffices in principle to justify an induction about causal connections: if it could be safely established in a single case that a given singular plant has a certain curative power, it could be correctly concluded by induction that all plants of the same species as this one do have similar curative powers. In conformity with the Aristotelian model, natural

philosophy in Ockham's view is an authentic science of necessary connections. Although the ontology is simplified with the help of sophisticated semantical analysis, traditional metaphysics is not abandoned (see Natural philosophy, medieval).

9 Natural theology

Theology, on the contrary, is not in the normal course of things properly called a science, according to Ockham, because it does not rest on the required sort of natural evidence. In his view a science, strictly speaking, is a set of cognitive *habitus* (see §4) having to do with necessary conclusions that were formerly dubitable for the agent but that became ascertained through syllogistic reasoning from self-evident general premises or well-established empirical generalizations. It is not so with theology, most of which rests on faith and revelation; the parts that can be demonstrated by natural reason alone are very thin indeed. Compared to most of his medieval predecessors, Ockham is quite sceptical with respect to a purely natural theology (see Natural theology).

First, no simple and proper concept of God, he holds, is accessible to human beings in this life. The human person in this life - frequently called the 'traveller' (*viator*) by medieval theologians - is characterized precisely by the fact of having no direct intuitive cognition of God. However, intuitive cognition of something is a prerequisite condition for the formation of any proper and simple abstract cognition of that thing (see §4), and therefore neither is any such cognition naturally possible in this life with respect to God. The only simple concepts applicable to God that a human being can naturally form are general concepts that will also signify other beings in one way or another. Some will be absolute (or quidditative) concepts (see §6), such as the general concept of 'being' which, according to Ockham, univocally applies to God and to creatures. However, most will be connotative or negative terms, such as 'creator' (which connotes the creatures) or 'immortal' (which negatively signifies death). A proper concept of God, for Ockham, is naturally constructible in this life only as a composite bundle of such general quidditative, connotative and negative concepts.

In the second place, even if some general or composite concepts applicable to God can naturally be formed, this will not suffice for the 'traveller' to *know* that these concepts apply to the Supreme Being. What would have to be known in addition is at least that such a being exists. One can easily form, for instance, the concept of an immortal being, simply by negatively referring to death, but this possibility in itself does not suffice to warrant the belief that such a concept does apply to anything real.

Can the existence of God be proven by natural reason? Ockham criticizes and rejects most of the alleged proofs of his predecessors. Anselm's celebrated argument, for one, is considered by him as valid only insofar as it proves that among actually existing entities there is at least one with respect to which none is greater (see Anselm of Canterbury). This is far from enough, in Ockham's eyes, to conclude that nothing could possibly be greater, if it existed. Consequently, the argument does not establish that the greatest possible being does exist in fact. Proofs from final causality, such as Aquinas' fifth way, do not work either because, Ockham says, it cannot be demonstrated that material things that lack cognition do act according to final causes pre-established by a will (see God, arguments for the existence of).

The proofs of God's existence that Ockham considers strongest are the arguments from efficient causality. However, these are not all equally conclusive, and even in the best cases they do not prove as much as most of his predecessors would have hoped for. Ockham admits as a self-evident principle that being cannot come from non-being, and concludes accordingly that every natural thing does indeed need to have been brought into existence by some external cause. But nothing, he adds, impedes in principle the possibility of an infinite regress in time in the series of such productive causes. Since no actual infinity would be involved, the past eternity of the material world is not philosophically impossible. What Ockham does deem impossible, on the other hand, is the existence of an actual infinity of simultaneous *conserving* causes; and this is the basis for the only relevant scientific proof he is ready to grant on this subject. Each caused thing, he believes, needs not only to be brought into existence, but also to be conserved in existence by some external cause (see Creation and conservation, religious doctrine of). Such a conserving cause must exist simultaneously with its effect as long as the effect exists, and the infinite regress in this case is consequently ruled out in principle since it would entail the existence of an actual infinity of distinct beings. This argument, then, does establish that there actually exists at any moment a first efficient conserving cause. What it does not prove, however, is that there should be only one such cause at any moment and that this cause should be identified with God: a celestial sphere or an angel could do equally well.

A fortiori, none of the other traditionally accepted characteristics of the Supreme Being can be proven by natural reason alone to be actually exemplified. In particular, it cannot be philosophically demonstrated, Ockham argues, that God is the first efficient cause of everything, that he is the final cause of something, that he is infinite or even that he knows anything. Articles of faith about God are not in general a matter for reason to settle. Rational argumentation is not ruled out of theology, of course - far from it - but its most crucial premises are accepted solely on the basis of religious faith. Some of the theological truths indeed even run counter to what natural reason by itself would favour: Ockham admits, for instance, that the doctrine of the Trinity involves the actual existence of distinct relational entities, something which, as a philosopher, he firmly rejects. In such cases, Ockham always clearly asserts the priority of the authority of the church over the pronouncements of reason and experience. Philosophy and theology nevertheless tend to be much less intertwined in his thought than they were in the thought of Aquinas or Scotus, for example.

10 Ethics

Ethics is especially interesting in this regard insofar as it simultaneously displays both the intimate interconnection and the relative independence of the philosophical and the theological outlooks. Ockham devoted no special elaborate treatise to ethics and nowhere systematically collected his views on the matter; but many scattered relevant developments in the commentary on the *Sentences*, the *Quodlibeta septem* and the collection known as the *Quaestiones variae (Various Questions)* do reveal, when considered together, an original two-sided theory of the object and foundations of moral knowledge (see Ethics).

Taken as a whole, moral science in this view is the practical normative knowledge of what is to be done, in general or under particular circumstances. It includes two distinct and independent parts. Positive moral science, on the one hand, is knowledge about the legal obligations one is formally subject to; it subdivides in turn into knowledge about human laws and knowledge about divine laws. Non-positive moral science, on the other hand, is directive knowledge about human action (or *praxis*) insofar as it is based on natural reason and experience. The former, says Ockham, is not a demonstrative science properly speaking, since it depends on human and divine precepts which are not evidently known *per se* or empirically. The latter, which corresponds to what Aristotle discusses in his own ethical books, is indeed a proper part of demonstrative philosophy, and it is even more certain and useful, Ockham insists, than many other sciences. It rests jointly on natural experience and on a number of general principles evidently known *per se*, such as: ‘what is honest should be done and what is dishonest avoided’, ‘benefactors deserve gratitude’, ‘the will should conform to the dictates of right reason’, and so on.

The philosophical part of ethics will shed light, in particular, on the general criteria of what is humanly laudable or blameworthy, even for a pagan. Ockham’s theses on this are characteristic. Only acts, according to him, can be morally good or virtuous; and among acts, only internal acts of the will can be rightly considered as *intrinsically* virtuous. Other sorts of acts, whether bodily or mental, are sometimes called ‘virtuous’, of course, but this is only ‘by extrinsic denomination’, exactly as a beverage is sometimes called ‘healthy’ not because it is itself in good health but because it has some salient causal relation with something else which is (or could be) intrinsically in good health. Ockham’s ethics, like Abelard’s, consistently stresses the basic moral character of intentions rather than that of outward behaviour (see Abelard, P.). His point is that for an act to be intrinsically virtuous, some necessary conditions need to be met that can be fulfilled only by internal acts of the will. First, it has to be free of internal necessity or external compulsion; it has, in other words, to be under the direct power of the will itself. Second, it has to conform to the dictates of what he repeatedly calls ‘right reason’ (*recta ratio*), which is the rational and well-informed use of prudence and moral conscience.

This notion of ‘right reason’ is central to Ockham’s philosophical ethics. The highest degree of moral virtue pagans can reach, according to him, precisely requires that they should will not merely to fulfil their moral obligations, but also that they should so will precisely in view of the fact that these obligations are dictated by right reason. Right reason, on the other hand, does not reduce to natural reason alone. It involves correct and prudential reasoning enlightened by whatever relevant true knowledge is available to the agent. In the case of the Christian believer, then, the dictates of right reason cannot be independent of the content of Christian faith. This is the exact point where non-positive moral demonstrative science yields, for Ockham, to a higher form of ethics: positive Christian moral science, as enlightened by religious faith.

This is not to say that philosophical moral science by itself is completely unreligious. Ockham explicitly holds, on the contrary, that reason suffices to demonstrate that there is at any time an actually existing *summum bonum*, and right reason, then, dictates, independently of any divine revelation, that nothing else ought to be loved more than this *summum bonum*. However, Christian revelation goes much further. It tells the believer, among other things, that this *summum bonum* is the unique God, that he is not only the highest good in fact, but also the highest possible good, that he is our creator and benefactor, that he is a personal knower and so on. Once these data from revelation are taken into account, right reason should lead the believer towards an even higher degree of moral virtue, which will correspond to Christian morality proper. It is reached when agents will to fulfil their obligations not merely because they conform to the dictates of right reason anymore, but primarily for the love of God himself and because these obligations derive from God's will. This alone is the level of perfect moral virtue.

The real ultimate foundation of ethical norms, then, turns out to be God's will and nothing else. The sole fact that God commands something to be done is what makes that thing morally good. God could at any time change his precepts and our moral obligations would then change accordingly. He could command, for example, that we should from now on steal whenever we can and it would *ipso facto* become morally good to do so. However, this is no longer demonstrative ethics; it is Christian theology based on revelation and on the indemonstrable principle of God's absolute supremacy. Even though religious faith leads him beyond philosophical ethics into what has often been called a 'divine command ethics', which ultimately plays a foundational role in his overall system, Ockham in the last analysis does not blur the distinction he had drawn between the two sorts of moral knowledge, and he never expresses serious doubts about the soundness of secular moral reasoning in the actual world.

11 Political thought

While Ockham had not ventured into political philosophy during his academic career in England, almost all the works he is taken to have written in Munich from 1330 to his death in 1347 are directly related to his conflicts with the Avignon papacy (with the possible exception of one short logical tract, the *Elementarium logicae (Elements of Logic)*). His goal at first was to expose the errors and heresies of Pope John XXII, especially about poverty within the church and about the beatific vision. This raised in effect the delicate question of papal heresy: who, in such a case, is entitled to denounce it? Who has the power to depose the Pope? Reflections on such matters progressively led Ockham to be more and more interested in political theory proper, and most of his writings after 1337 were directly devoted to it, notably the *Octo quaestiones de potestate papae*, Book III of the *Dialogus* and the *De Imperatorum et Pontificum potestate*.

In this endeavour, Ockham primarily thought of himself as a theologian. Many of his arguments against the Avignon curialists were designed for the ecclesiastical community and based on the Bible, the writings of the Church Fathers or canon law. However, he also liberally used Aristotle's *Politics* and much of his thought in this field can be seen, in fact, as being in direct continuation with his philosophical ethics of right reason: politics, after all, is but a province of human *praxis*.

Indeed, Ockham's basic political idea is that the spiritual and the temporal powers should normally be kept apart and not be allowed to overlap, except in special cases of crisis such as papal heresy or tyrannical abuse. On the whole, he found much to say in favour of the institution of papacy, but he energetically opposed the papalist doctrine of the *plenitudo potestatis* of the Pope and emphatically denied the dependence in principle of secular on ecclesiastical power. The church, he thought, should as a general rule disentangle itself from worldly politics. Consecration by the Pope, for example, was not in his view a necessary condition for the legitimacy of the Emperor.

What then is the basis for the legitimacy of secular political power? Popular consent, according to Ockham, is the normal original source of legitimacy; but beyond this, the rightness of a certain political regime ultimately depends on how well it fulfils its functions. Government is instituted for the good of a community of individual subjects, and if a regime adequately performs this task, it is not legitimate, for the Pope or even for the majority of subjects, to try to overthrow it by force. Ockham's approach to politics is basically functional. What he thinks should be expected from a government is mainly that it should prevent and punish injustice and so preserve in this way the rights and freedom of the individual members of the community. Monarchy, for him, is usually the best regime insofar as it is, in most circumstances, best suited to such a role; but there is nothing absolute - or divinely founded - in this judgment in Ockham's eyes. A political regime is a man-made institution to be judged by its expediency in

achieving the goal for which it should ideally be designed: and common welfare or public security can in principle be enhanced by different regimes in different circumstances.

Natural rights, in this perspective, are what a government is expected to protect (see Rights). Ockham never gave a systematic account of these rights, but examples of them in his writings include the individual's right to the necessities of life, the collective right for a people lacking a ruler to choose one, the right to resist an unjust government, and so on. As a general rule, the rights and obligations of rulers and subjects, he thought, can be determined in particular circumstances by the normal prudential use of human right reason. Ultimately, what the political and legal institutions should be aiming at preserving is the individual freedom of the members of the community in their own private spheres.

At the same time this respect for freedom sets a limit in principle to the exercise of any political power, whether ecclesiastical or secular: 'free persons, who are not slaves', Ockham writes, 'should never, without some fault, be compelled by new laws to do things which are not necessary to the commonwealth or to their neighbour' (*Breviloquium de potestate Papae* II, 17). Political rule should be kept to the minimum which is required in any circumstances for the fulfilment of its social functions.

It has often been wondered whether Ockham's political thought is dependent on the rest of his philosophy, and on his nominalism in particular. Certainly his political theories were not deduced from nominalistic premises in ontology, theory of knowledge or philosophy of language. He never defended his political stands by arguments drawn from these fields, and his conceptions of ecclesiastical and political power are compatible with different ontological or epistemological doctrines. Moreover, probably because of the new audience he was trying to reach, he did not make much use in his political writings of the technical tools of semantical analysis which he had so extensively exploited in theology and philosophy. Nevertheless, the break between the two parts of his work is far from complete. Ockham's approach to politics and natural rights is in direct continuation with his philosophical ethics of right reason. And, more importantly, the emphasis of his later writings on personal freedom can certainly be seen as the political counterpart of the accent on singularity which was the trademark of his nominalism. Even though there is no logical connection here, both aspects of Ockham's thought harmoniously fall in line with each other in consistently stressing the primacy of individuals.

CLAUDE PANACCIO

List of works

1 Critical editions

William of Ockham (1317-47) *Opera Philosophica et Theologica (Philosophical and Theological Works)*, eds G. Gál *et al.*, St Bonaventure, NY: The Franciscan Institute, 1967-88, 17 vols.(Excellent critical edition of all of Ockham's non-political writings, subdivided into two series: *Opera Philosophica*, 7 vols, and *Opera Theologica*, 10 vols. A selection of basic philosophical texts can be found in English translation in P. Boehner, *Ockham: Philosophical Writings*, London: Nelson, 1957.)

William of Ockham (1332-47) *Opera Politica (Political Works)*, eds H.S. Offler *et al.*, Manchester: The University Press, 1956-74, vols I-III; Oxford: Oxford University Press, 1997, vol.IV.(Still incomplete; it lacks in particular the very important *Dialogus*. A selection of political texts, most of which come from the *Dialogus*, can be found in English translation in A.S. McGrade and J. Kilcullen, *William of Ockham: A Letter to the Friars Minor and Other Writings*, Cambridge: Cambridge University Press, 1995.)

2 Major works

William of Ockham (1317-19) *Ordinatio. Scriptum in librum primum Sententiarum (Commentary on the First Book of the Sentences)*, in *Opera Theologica*, St Bonaventure, NY: The Franciscan Institute, vols I-IV.(The basic work for Ockham's epistemology, ontology and theology; partly revised 1320-6.)

William of Ockham (1317-19) *Reportatio. Quaestiones in libros Sententiarum II-IV (Questions on Books Two, Three and Four of the Sentences)*, in *Opera Theologica*, St Bonaventure, NY: The Franciscan Institute, vols

V-VII.(Authorized students' notes; a useful complement to the *Ordinatio*.)
William of Ockham (1317-24) *Quaestiones variae (Various Questions)*, in *Opera Theologica*, St Bonaventure, NY: The Franciscan Institute, vol. VIII.(Eight developments on various points such as the language of angels, the interrelations between virtues and so on.)
William of Ockham (1319-21) *Summula philosophiae naturalis (Synopsis of Natural Philosophy)*, in *Opera Philosophica*, St Bonaventure, NY: The Franciscan Institute, vol. VI.(Unfinished work: Ockham's first attempt at physics.)
William of Ockham (1320-3) *Expositio in librum Porphyrii de praedicabilibus (Commentary on Porphyry's Treatise on the Predicables)*, in *Opera Philosophica*, St Bonaventure, NY: The Franciscan Institute, vol. II.(Mainly on universals.)
William of Ockham (1320-3) *Expositio in librum praedicamentorum Aristotelis (Commentary on Aristotle's Categories)*, in *Opera Philosophica*, St Bonaventure, NY: The Franciscan Institute, vol. II.(Introduce's Ockham's nominalistic interpretation of Aristotle's ten categories.)
William of Ockham (1320-3) *Expositio in librum Perihermenias Aristotelis (Commentary on Aristotle's De interpretatione)*, in *Opera Philosophica*, St Bonaventure, NY: The Franciscan Institute, vol. II.(Contains one of Ockham's most detailed discussions on the mental existence of concepts.)
William of Ockham (1320-3) *Tractatus de praedestinatione et de praescientia Dei respectu futurorum contingentium (Treatise on Predestination and God's Foreknowledge of Future Contingents)*, in *Opera Philosophica*, St Bonaventure, NY: The Franciscan Institute, vol. II; trans. M.M. Adams and N. Kretzmann, *William of Ockham: Predestination, God's Foreknowledge, and Future Contingents*, Indianapolis, IN: Hackett, 2nd edn, 1983.(How to reconcile God's infallible knowledge with the contingency of future events.)
William of Ockham (1322-4) *Expositio super libros Elenchorum (Commentary on Aristotle's Sophistical Refutations)*, in *Opera Philosophica*, St Bonaventure, NY: The Franciscan Institute, vol. III.(Ockham's theory of logical fallacies.)
William of Ockham (1322-4) *Tractatus de quantitate et Tractatus de corpore Christi (Treatise on Quantity and Treatise on the Body of Christ)*, in *Opera Theologica*, St Bonaventure, NY: The Franciscan Institute, vol. X; trans. B.T. Birch, *The De Sacramento Altaris of William of Ockham*, Burlington, IA: The Lutheran Literary Board, 1930.(Mainly on the semantics of quantitative language; Birch's translation should be used with caution.)
William of Ockham (1322-4) *Brevis summa libri Physicorum (A Short Summary of the Book of Physics)*, in *Opera Philosophica*, St Bonaventure, NY: The Franciscan Institute, vol. VI; trans. J. Davies, *Ockham on Aristotle's Physics*, St Bonaventure, NY: The Franciscan Institute, 1989.(Ockham's shortest physical work; a useful synthesis of his views on motion.)
William of Ockham (1322-4) *v(Questions on the Physics of Aristotle)*, in *Opera Philosophica*, St Bonaventure, NY: The Franciscan Institute, vol. VI.(151 Questions on concepts, change, motion, time, place and related subjects.)
William of Ockham (1322-7) *Expositio in libros Physicorum Aristotelis (Commentary on the Physics of Aristotle)*, in *Opera Philosophica*, St Bonaventure, NY: The Franciscan Institute, vols IV-V.(Ockham's largest and most important work on physics.)
William of Ockham (1322-7) *Quodlibeta septem* (Quodlibetal Questions), in *Opera Theologica*, St Bonaventure, NY: The Franciscan Institute, vol. IX; trans. A.J. Freddoso and F.E. Kelley, New Haven, CT: Yale University Press, 1991, 2 vols. (A set of 170 short questions giving Ockham's latest views on important philosophical and theological subjects.)
William of Ockham (1322-7) *Summa logicae (Summa of Logic)*, in *Opera Philosophica*, St Bonaventure, NY: The Franciscan Institute, vol. I; Part I trans. M.J. Loux (1974) *Ockham's Theory of Terms*, Notre Dame, IN: University of Notre Dame Press; Part II trans. A.J. Freddoso and H. Schuurman (1980) *Ockham's Theory of Propositions*, Notre Dame, IN: University of Notre Dame Press. (The basic work for Ockham's semantics and logic.)
William of Ockham (1332-4) *Opus nonaginta dierum (The Work of Ninety Days)*, in *Opera Politica*, Manchester: The University Press, vols I-II. (A detailed discussion of Pope John XXII's ideas on poverty.)
William of Ockham (1334-47) *Dialogus (The Dialogue)*, Lyons, 1494-6; repr. London: Gregg Press, 1962. (Ockham's major political synthesis; unfinished.)
William of Ockham (1334-5) *Tractatus contra Ioannem (Treatise Against John)*, in *Opera Politica*, Manchester: The University Press, vol. III.(Argues that Pope John XXII, who had just died, was a heretic despite his supposed final 'retractation'.)
William of Ockham (1337-8) *Tractatus contra Benedictum (Treatise Against Benedict)*, in *Opera Politica*,

Manchester: The University Press, vol. III.(A discussion on papal heresy and the nature of the church; attacks Pope Benedict XII for not having reproved the errors of his predecessor.)

William of Ockham (1338-9) *Compendium errorum Papae Ioannis XXII*, Lyons, 1495; repr. London: Gregg Press, 1962; in *Opera Politica*, Oxford: Oxford University Press, 1997, vol. IV.(Synthesizes Ockham's doctrinal critique of John XXII.)

William of Ockham (1339-40) *Breviloquium de potestate Papae (A Short Discourse on the Power of the Pope)*, ed. L. Baudry, Paris: Vrin, 1937; trans. A.S. McGrade and J. Kilcullen, *William of Ockham: A Short Discourse on Tyrannical Government*, Cambridge: Cambridge University Press, 1992.(On the relations between the power of the Pope and that of the Emperor.)

William of Ockham (1340-1) *Octo quaestiones de potestate Papae*, in *Opera Politica*, Manchester: The University Press, vol. I.(On various questions concerning the alleged authority of the Pope over the Emperor.)

William of Ockham (1340-7) *Elementarium logicae (Elements of Logic)*, in *Opera Philosophica*, St Bonaventure, NY: The Franciscan Institute, vol. VII.(An interesting logical treatise, but its authenticity is still doubtful.)

William of Ockham (1346-7) *De imperatorum et pontificum potestate (On the Power of Emperors and Popes)*, ed. C.K. Brampton, Oxford: Clarendon Press, 1927; part ed. W. Mulder in *Archivum Franciscanum Historicum* 16, 1923: 469-92, and 17, 1924: 72-97; in *Opera Politica*, Oxford: Oxford University Press, 1997, col. IV.(A final discussion of civil and papal powers.)

William of Sherwood (*c.*1200/5-*c.*1266/75)

William of Sherwood, an English logician of the mid-thirteenth century, is most noted for his theories of supposition and syncategorematic terms. In application, these theories enable us to express the true logical form of sentences with misleading grammatical forms. William's Insolubilia (Insolubles) deals with paradoxes of self-reference, such as 'I am now uttering a falsehood'.

William, who was born probably in Nottinghamshire, studied at Oxford and became a master there. Roger Bacon praised him as a greater logician than Albert the Great. His *Introductiones in logicam (Introduction to Logic)* includes five chapters on traditional logic, corresponding to Aristotle's *On Interpretation*, *Prior Analytics*, *Topics* and *Sophistical Refutations* (see Aristotle) and Porphyry's *Isagōgē* (see Porphyry), and it is typical of its time in its reliance on Boethius for much of what it says about the traditional topics.

The most interesting chapter of *Introductiones in logicam* is the one on the 'properties of terms', a logical doctrine that originated in the twelfth century. In William's account, the first of these properties is signification, the 'presentation of the form of something to the understanding'. This is the meaning of a term taken in isolation from its context, and specified extra-linguistically. Sometimes the signification of a term has nothing to do with its use in a sentence and the term 'supposits for' itself, as in 'man is a monosyllable'; this is material supposition. A term also supposits a form in a sentential context if its use there reflects its signification, so that it supposits *for* the form itself or something subordinate to it; this is formal supposition, in which a term supposits for an 'understanding of something' or, as William of Ockham might have said, for a mental term.

'Copulation' is parallel to supposition but belongs to adjectives and depends on a signification of something not as existing, but as adjoined to what exists. A term's 'appellation' is the set of those things of which the term can be predicated truly in the present tense. In an ordinary present-tense sentence a term's supposition will not extend beyond its appellation, for its subject can only supposit for actually existing things. The form that a term signifies does not of itself provide reference, then, unless the term supposits for the form itself in simple supposition, as in 'man is a species'. Otherwise, the term depends on existing individuals for its reference, a view consistent with nominalism, permitting us to take the form supposited for in simple supposition as an 'understanding of something', or a mental term, acquired through acquaintance with individuals, which are the term's primary referents. Thus William's views contrast with those of Peter of Spain, which reflect a realist stance.

Usually a term supposits for individuals (or, to be precise, concepts of individuals) falling under the form it signifies, which is personal supposition. Personal supposition is 'determinate' when a word supposits for a single unspecified individual, as in 'a man is running', and 'confused' when a word supposits for more than one thing. Confused personal supposition is 'mobile' if one is entitled to attach its predicate to each of the individuals for which the term supposits, and is otherwise 'immobile'. Rules concerning personal supposition were used to assess the validity of arguments treated nowadays with quantification theory, but supposition occurs within a natural language, and no artificial language adapted to the uses of logic had been constructed. As a result, an open-ended set of rules governing the different types of supposition was introduced to handle all sorts of special contexts in scholastic Latin.

William's *Syncategoremata (Treatise on Syncategorematic Words)* extends supposition theory to sentences containing words that produce a misleading grammatical form, sometimes by altering the supposition of associated terms or concealing the true logical subject, and sometimes by abbreviating composite statements and making them appear categorical. Such words include 'every', 'whole', 'all', 'both', 'nothing', 'but', 'only', 'necessarily', 'begins', 'unless' and many others.

Also attributed to William, though doubtfully, are the treatises *De petitionibus contrarium (On Contrary Assumptions)* and *Insolubilia (Insolubles)*, and an *Obligationes* which is probably by Walter Burley. The *Insolubilia* deals with semantic paradoxes of self-reference. For instance, when one utters 'I am now saying a falsehood', William insists that the sentence is meaningful and rejects the general rule excluding any reference within a sentence to itself, since some self-referential sentences make perfect sense and are true. Rather, he appeals to the principle of charity and takes it that the sentence refers outside itself in this case, since it is otherwise absurd.

Thus, those who utter ‘I am now saying a falsehood’ assert that they are saying some falsehood other than the sentence they utter, which is, of course, false (see Semantic paradoxes and theories of truth).

Williams, Bernard Arthur Owen (1929-)

Bernard Williams has written on the philosophy of mind, especially personal identity, and political philosophy; but the larger and later part of his published work is on ethics. He is hostile to utilitarianism, and also attacks a view of morality associated in particular with Kant: people may only be properly blamed for what they do voluntarily, and what we should do is the same for all of us, and discoverable by reason. By contrast Williams holds that luck has an important role in our evaluation of ourselves and others; in the proper attribution of responsibility the voluntary is less central than the Kantian picture implies. Williams thinks shame a more important moral emotion than blame. Instead of there being an independent set of consistent moral truths, discoverable by reason, how we should live depends on the emotions and desires that we happen to have. These vary between people, and are typically plural and conflicting. Hence for Williams ethical judgment could not describe independent or real values - by contrast with the way in which he thinks that scientific judgment may describe a real independent world.

1 General

Bernard Williams studied philosophy and classics at the University of Oxford. He was later Professor of Philosophy in London, Cambridge, Oxford and Berkeley, California, as well as chairing the commission set up by the British Government in 1977 to consider the legal control of obscene material.

Williams has written about many different areas of philosophy. His books include full-length studies of Descartes and of early Greek ethical thought, and he has written extensively on the philosophy of mind. His most influential writing has been in ethics, where he wrote *Morality* (1972), a book which pretends to be introductory but is in fact much more, *Ethics and the Limits of Philosophy* (1985), a criticism of utilitarianism (the ‘against’ half of *Utilitarianism: For and Against* (1973a)), and many occasional papers, the most important of which are collected in *Moral Luck* (1981b).

Before turning to this ethical work two important early papers on other areas should be mentioned. His first collection, *Problems of the Self* (1973b), starts with a paper on personal identity. Williams takes an imaginary case in which twin brothers both claim to remember being the same historical figure. This shows that memory claims are not sufficient to establish personal identity (since the twins, being different from each other, cannot both be the earlier person). Hence, thinks Williams (although this would involve another argumentative step), the necessity of bodily identity for personal identity. This paper’s use of duplication is the basis of much of the subsequent discussion (see Personal identity).

Another influential early paper in this collection is ‘The Idea of Equality’. Williams here argues that some activities have an internal object, so that, for example, the internal object of the provision of medical services is medical need. Hence it is not optional whether health care should be distributed according to health need or according to ability to pay. By solving the problem of relevance in this way, Williams solves the problem of which property to consider in distribution, and hence a central problem of making egalitarian proposals practical (see Equality).

2 Morality, the peculiar institution

Williams, like other philosophers, often works by critique and contrast. The centre of his ethical position can best be brought out by considering what he takes himself to be opposing. This is a view of morality principally associated with Kant. In this view, morality imposes on all people a set of duties discoverable by reason alone. These obligations are taken to be objectively true, untouched by emotion and unconstrained by interest. The area of morality is meant to be sharply distinguishable from other practical concerns and to be particularly connected to the voluntary. For Kant, we can all equally will and are equally responsible for, and only for, what we will (see Kantian ethics).

All this Williams criticizes. He resists even the word ‘morality’, preferring the term ‘ethics’ for the study of how we should live. The voluntary he regards as too weak a notion to found obligation. He holds that our moral psychology and ethical intuitions reveal our values to be more tangled, pluralist and impure than the Kantian model allows. Kantianism is centred on obligation and blame. Instead of blame, Williams proposes the centrality

of shame. He discusses the nature of shame by considering the thought of the early Greeks, which he thinks is more applicable to the actuality of our current practical thinking than Kant's idealization. For Williams, Kant is wrong on the psychological facts; on the nature of the person; and on motivation. Kant is wrong to exclude the emotions. By contrast, Williams uses emotions, particularly regret, as a tool to uncover ethical requirements (see Morality and emotions; Praise and blame).

Perhaps the topic that focuses these thoughts most fully is that of moral luck. In the Kantian model, moral evaluation of people cannot depend upon mere luck (hence the importance of intention: there may be luck whether people succeed; there is no luck about whether they try). Williams wishes to show instead that our central evaluations may depend upon luck. For example, if I drive my car carefully and through no fault of my own run over a child, I may still, according to Williams, feel what he calls 'agent-centred regret' (that is, not just regret that it happened, but also regret that I did it). I may feel it proper to try and make some sort of recompense or acknowledgement of my responsibility. Yet my intentions were impeccable; if nevertheless regret is an appropriate emotion, it is a product of pure bad luck in a way that the Kantian model would preclude.

Williams' central example is the case of Gauguin (and a picture of Gauguin is used to illustrate the cover of *Moral Luck*). Gauguin left his wife and family to go to the South Seas to paint great pictures. If he succeeds he is justified; if he doesn't he is reprehensible. Again, mere intention is not enough; proper evaluation depends upon the luck of success (see Moral luck).

3 Internal and external reasons

For Kant, once I know that something is the right thing to do (which I am supposed to be able to do by pure reason alone, uninfluenced by desire), this alone supplies me with a reason for action. This Williams resists. He calls such reasons 'external' reasons, and wants to argue, by contrast, that reason can only motivate me if it is connected to some already existing motivational state of myself (such as a desire). Such reasons Williams calls 'internal' reasons, because they follow from something internal to the agent. Williams' terminology here needs care and is liable to be confusing as he uses these terms in a different manner and with opposite effect than most philosophers (for whom 'internal' is taken to mean internal not to the person, but to morality; in the standard use, a reason based on antecedent desire is hence 'external').

In Williams' terminology, all reasons (that is, all real reasons) are internal reasons. That something, for example, follows from the rationally apprehended supposed requirements of justice gives me in itself no reason to do it. I only have a reason if I also happen to want to be just. For Williams it is the same with prudence. Some philosophers, such as Sidgwick, argue that I am rationally required to regard all times to be of equal value; Williams, by contrast, argues that I only have a reason to consider the distant future as important as the near future if I happen to have a particular kind of prudential psychology. Again, what counts as a reason for me depends upon my own idiosyncratic psychological state; pure reason alone is unable to tell me what to do (see Moral motivation).

4 Utilitarianism

Williams also attacks utilitarianism, which shares with Kantianism the claim that morality has an impartial and objective foundation. Williams attacks the idea that the plurality of values can be reduced to a single metric. He probes the question of whether utilitarians can properly think that they are utilitarians. However, his central objection is again in terms of the impossible psychology that the moral theory demands.

In utilitarianism everything is justified by the consequences. In criticism, Williams wants to show that it is important not just what happens but also who does it. He takes the example of someone having the choice of doing a terrible thing, such as killing someone, in order to prevent more deaths being caused by someone else. For utilitarianism, which just counts the number of deaths, the answer is simple. But for Williams the answer is not simple; which shows that we are also concerned with who does the killing. He puts this in terms of people's integrity: there are things which people cannot be expected to do, whatever the consequences, if they are to be able to preserve any sense of themselves as people, or agents, at all (see Utilitarianism).

5 Consistency and realism

In two early papers Williams attempts to show that moral judgments are much more analogous to desires than to beliefs. Where there is a conflict of beliefs, he argues, this must in itself tend to weaken at least one of the beliefs, since beliefs are aimed at truth and two contradictory beliefs cannot both be true. Yet inconsistent desires are not like this. Although they cannot both be satisfied, this has no tendency to weaken at least one of them.

Williams shows that in tragic cases someone may be under two incompatible obligations, as Agamemnon in classical Greek tragedy was under incompatible obligations to his daughter and to his fleet. Whatever he does is wrong. On a Kantian view such conflict would not be possible; and it would not be rational to feel guilt about the thing not done. Yet Williams, again using moral psychology, shows that we both do and should feel regret in this sort of case. Hence what we did was wrong; hence there were incompatible obligations.

He derives from this conclusions about moral realism. The possibility of contradictory obligations shows that they cannot be taken to be descriptions of some real, independent, moral state of affairs. Our evaluative beliefs are plural and conflicting. They are therefore not descriptions of independent values which would provide objective and impersonal reasons for action (see Berlin, I.; Moral pluralism).

So far this is similar to other twentieth-century departures from the abstract impersonal reason of the Enlightenment. However, Williams disagrees with other thinkers in making a sharp distinction between ethical and other beliefs. For him, ethics is strongly contrasted with science. Both can be called kinds of knowledge, in that there can be agreement of belief about them. However, for Williams, this does not survive reflection in ethics, whereas in science it can. Scientific knowledge converges and can also explain how our scientific beliefs are caused by a real, independent world. Moral beliefs cannot in the same way survive explication of their causes.

An idea which Williams originally discussed in his book about Descartes, and which can be used to underline this distinction, is that of the ‘absolute conception’ of reality. Our knowledge and belief is perspectival, or from a particular position. Yet we have also the idea of things being true absolutely; that is, not from any particular position. This applies, thinks Williams, in science; at least as a regulative ideal. Things are just true; even if we do not know them. However, in ethics, it is all from a position. It is not just that it is psychologically impossible to think of ourselves being motivated by supposed moral truths which are true for all peoples and for all times; it is not just that our variable ideas show that we have no knowledge of any such truths; it is also that there are no such truths to be known.

Wisdom

*In ancient times, wisdom was thought of as the type of knowledge needed to discern the good and live the good life. Philosophy takes its name from it (*philosophía *means love of wisdom). But wisdom is little evident as a subject of contemporary philosophical discussion. It is interesting to ask how the concept of wisdom has come to vanish almost entirely from the philosophical map.*

1 Classical views of wisdom

Among the classical Greeks, wisdom (*sophia*) was one of the principal four virtues or human excellences (*aretai*), along with justice, moderation and courage, and was the primary focus of all epistemological discussion. In Plato's early dialogues, we find Socrates portrayed as a man on a mission given him by the god of Delphi (Apollo). Socrates tells the story (in Plato's *Apology*) that his friend Chairephon approached the oracle and asked if anyone was wiser than Socrates. The oracle answered 'no'. When Chairephon reported this encounter to Socrates, the latter found it deeply puzzling, for he regarded himself as not at all wise. In seeking to unravel the riddle of the oracle, Socrates questioned others who had the reputation for wisdom, and learned that he was indeed the wisest of men, for he alone recognized that he lacked wisdom. The mission of Socrates on behalf of the god, therefore, was to examine anyone willing to submit to his questioning, to see if they were wise and, if not, to 'assist the god' (*Apology* 23B) by showing that they are not. The pursuit of wisdom, then, and the exposure of the pretence of wisdom, was at the heart of Socratic philosophizing.

If Plato's early dialogues tell us anything about the historical Socrates, they show that, for him, wisdom would provide its possessor not only with all the other virtues (through Socrates' commitment to the 'unity of the virtues'), but also with infallible judgment in one's pursuit of a good or happy (*eudaimōn*) life. Some scholars even suppose that Socrates regarded the possession of wisdom as both necessary and sufficient to having a good or happy life, but this is controversial and seems to yield the result that no one could have a good or happy life, despite the fact that at least Socrates himself seems to have had one. Plato's early-period Socrates also recognizes minor and particularized forms of wisdom (each true craftsman would be wise in his craft, for example - see *Apology* 22C-D), but seems to regard these as philosophically insignificant, except as providing small-scale models for the really important form, which one could use in pursuit of a good and happy life. Wisdom, for Socrates, invariably requires the possession of knowledge, and not just any knowledge, but that which provides the basis for infallibly good judgment in decisions pertinent to how one should live. Wisdom, then, is the possession of such knowledge plus the disposition and skill to use this knowledge in the right ways.

In later works, Plato increasingly neglects the specific, craft-related wisdoms, coming eventually to identify wisdom only with the kind of knowledge that permits one to be infallible in judging the good. In the *Republic*, for example, Plato envisages a class of philosophical rulers who, through extensive training in mathematics and dialectic, will come to know the Form of the Good. This knowledge, we are told, will give the philosopher-rulers the fully actualized power to make infallible judgments in the state, seeing clearly, as it were, which institutions and political decisions were most just.

Aristotle is critical of Plato's theory of Forms in general, and of Plato's conception of the Good in particular. Aristotle's conception of the 'Four Causes' (*aitiai*) and his views about the categories of being require that there is a specific good for each thing - Plato's idea that there must be one Good for all things seems to Aristotle to be an absurdity (*Nicomachean Ethics* I.6; *Eudemian Ethics* I.8). Accordingly, Aristotle cannot see wisdom as requiring some vision of the Good. Aristotle accepts the infallibilism inherent in the Socratic and Platonic accounts, but divides wisdom into two sorts: theoretical and practical. Theoretical wisdom (*sophia*) is *nous* (the ability to grasp first principles) plus *epistēmē* (scientific knowledge or understanding - see *Nicomachean Ethics* VI.7), which involves knowledge of the 'causes' - the 'why' of things (*Metaphysics* A.1-2). In so far as there can be different sciences with different first principles, there can be different examples of theoretical wisdom - one for each science. Practical wisdom (*phronêsis*), for Aristotle, is knowledge of means and ends. Some have criticized this view as being insufficiently attentive to which ends are, and which could not be, the right ends for a wise person. This criticism, however, is controversial, and depends upon the degree to which Aristotle thought the study of ends could itself be scientific.

2 Later conceptions of wisdom

After Aristotle, wisdom begins to lose its place of primacy within philosophical discourse, no doubt partly due to Sceptical attacks, and partly due (later) to Christianity. The Sceptics rarely discussed wisdom. They appear to have accepted something like the Aristotelian account of theoretical wisdom, but then cast doubt on our ability to grasp first principles by arguing that even the most rudimentary and particular forms of knowledge - such as grasping some particular fact - are problematical. Sceptical practical wisdom, such as it was, became something like the ability to withhold assent from any particular proposition, thus avoiding dogmatism and achieving quietude (*ataraxia*). The connection with knowledge was thus either broken (for practical wisdom) or required a vast and difficult defence of knowledge (for theoretical wisdom) before philosophy could even return to wisdom as a subject of study. To a substantial degree, contemporary philosophy, and its preoccupations with justification and information, continues to focus its energies on the areas problematized by the ancient Sceptics.

Early Church Fathers, on the other hand, were generally suspicious of what the Greeks had identified as wisdom. They generally agreed that wisdom at best subserved Christian faith (see, for example, Augustine’s *City of God* 8.8); at worst they simply identified it with useless and deceitful book-learning and arrogant intellectual presumption, perhaps following St Paul’s warning against philosophy in *Collossians* 2: 2-8 (see, for examples, Justin Martyr *Dialogue with Trypho* 2.4-5, 7.1; Tertullian *Apology* 46.5-8). Subsequent epistemological disputes within religious contexts have also largely failed to revive wisdom as an object of rational pursuit, instead attending mainly to the degree to which various religious claims can or cannot be justified.

Wisdom can be found among medieval conceptions of the virtues, but it no longer held the central place it had been afforded by the Greeks. By the time we reach the early modern period, we find wisdom mentioned only rarely, and then only at the periphery of greater works (as in the preface to the French edition of Descartes’ *Principles of Philosophy*), or in revivals of ancient Greek points of view (as in the neo-Sceptical work, *De la sagesse* by Pierre Charron). From this period on, wisdom is mentioned only in passing, or simply passed by altogether by philosophers.

Given its disappearance from our discussions, none of the claims by the early Greeks has been sufficiently well scrutinized by philosophers. It is interesting, for example, that the development of fallibilism in epistemology has not served to liberate wisdom from its early association with infallibility, which was guaranteed to make wisdom seem an impossible achievement for human beings (see Fallibilism). On the other hand, the early connection between wisdom and some notion of a good life seems exactly right, but contemporary philosophy is deeply divided over what makes a life good. Perhaps as the criteria for human knowledge relax and conceptions of the good life (or good lives) become clearer, philosophy will find that it can return to the study of wisdom.

Witherspoon, John (1723-94)

John Witherspoon, Scottish-American clergyman, political leader and educator, was born at Gifford, East Lothian, educated at Edinburgh University and ordained Presbyterian minister. In his mid-forties he went to America as president of the College of New Jersey, later Princeton University. He held political office for New Jersey and played a major role in organizing the Presbyterian Church in America and improving the College at Princeton. Witherspoon was representative of eighteenth-century Scottish and American Calvinists who tried to reconcile their orthodox theological doctrines with the Enlightenment's philosophical currents of empiricism, scepticism, and utilitarianism by harmonizing reason and revelation. Although Witherspoon was a philosophical eclectic, Francis Hutcheson's moral sense philosophy was the major source of his utilitarian ethics and republican politics. Witherspoon was not an original thinker, but his popularization of Scottish common sense and moral sense philosophy through his forceful personality and effective teaching laid the foundation for its dominance of nineteenth-century American academic philosophy.

John Witherspoon was born at Gifford, East Lothian, Scotland on 5 February 1723 and died at Princeton, New Jersey, United States of America on 15 November 1794. A man of action but also of reflection, Witherspoon combined a strong interest in philosophical and theological questions with clerical, educational, and political activism. In Scotland (1723-68), he was a notable parish minister, theologian, and ecclesiastical politician in the Church of Scotland. Witherspoon gained fame in America (1768-94) as a cleric, educator, philosopher, and national leader in Church and state as president of the College of New Jersey, later Princeton University.

Witherspoon wrote numerous works on a wide variety of subjects, most notably moral philosophy, rhetoric, and theology. His divinity lectures, sermons and theological treatises stressed the practical ethics of orthodox Calvinist dogma: God's sovereignty; the individual's sinful nature; God's justification of the sinful through Christ; scriptural authority; and regeneration (see Calvin, J.).

Witherspoon's introduction to philosophy began as an Edinburgh University student with the epistemological empiricism of John Locke and the logic and moral philosophy of Johann Gottlieb Heineccius. He continued to read widely in philosophy during his Scottish years, but he only wrote two brief works on philosophy of religion. His 1739 university graduation thesis on the immortality of the mind relied on traditional philosophical and theological arguments, while his 'Remarks on an Essay on Human Liberty' (1753) attempted to refute Kames' position on the freedom of the will (see Home, H. (Lord Kames)) using a naïve version of Thomas Reid's common sense realism (see Reid, T.; Common sense school). Both works attempted to reconcile the conflicting claims of reason and revelation in defence of Calvinism against the attacks of philosophical sceptics.

Witherspoon's Scottish intellectual background provided the basis for his outstanding American career as churchman, educator, philosopher and politician. As Princeton's president (1768-94), Witherspoon stressed the unity of learning and piety in its curriculum. Required to teach philosophy for the first time, Witherspoon's most important contribution was his course on moral philosophy. His *Lectures on Moral Philosophy* (1768) derived from a wide variety of modern philosophers, but their eclectic nature caused him to make numerous philosophical errors. They were based primarily on Scottish thought, especially Hutcheson's moral sense philosophy, interpreted in the context of Witherspoon's Calvinism (see Hutcheson, F.; Moral sense theories). Although the organization and subjects of the *Lectures* closely followed Hutcheson's works, they did not simply mimic Hutcheson's ideas, for on critical points Witherspoon's arguments expanded on and took different positions from Hutcheson's.

Throughout his nine brief lectures on ethics Witherspoon's epistemology rested on his claim that reason and revelation combined to provide the foundations of human knowledge. But like Hutcheson, he was also a social Newtonian who conceived of moral philosophy an as empirical science of human beings and society, based on reason and independent of revelation. Ethics was 'that branch of Science which treats the principles and laws of Duty or Morals' (Witherspoon 1768: 269). Individuals acquired their knowledge of the world through external and internal senses. Witherspoon attacked Berkeley's idealism, which he found at Princeton (see Berkeley, G.) and replaced it with Reid's realism. In his faculty psychology he agreed with Hutcheson that the operations of the affections or passions were more important mental processes than the understanding or the will, but added religious affections to Hutcheson's incomplete catalogue of feelings.

The critical faculty was the moral sense, because it allowed persons to judge actions as evil or good. Joseph Butler’s concept of conscience influenced both Hutcheson and Witherspoon, although Witherspoon mistakenly equated the moral sense ’with what, in scripture and common language, we call conscience’ (1768: 281) (see Butler, J. §3; Conscience). Contrary to Hutcheson, Witherspoon followed Reid in arguing that reason played a critical role in aiding the moral sense to discover moral truth. The moral sense provided the philosophical linkage between Witherspoon’s epistemological, psychological and moral ideas and his theological doctrines. Since it originated in God, it bound all persons to the creator in a moral relationship. Thus, the moral sense harmonized reason and revelation. Witherspoon adopted Hutcheson’s utilitarian position ‘that benevolence or public affection is virtue, and that a regard to the good of the whole is the standard of virtue’ (1768: 285). As to the obligation of virtue, he favoured duty over interest, because the moral sense intimates ’that it is duty independent of happiness’ (1768: 291). Benevolence was the central virtue in motivating persons to the duties they owed God, their fellow human beings, and themselves. Witherspoon’s discussion of rights emphasized the inalienable rights of intellectual, political, and religious liberty as well as self-preservation.

Witherspoon’s political thought, explicated in three short lectures on politics, domestic society and civil society, was a logical extension of his ethics as a science of society. His republican political ideas, like his ethics, were eclectic, generally followed Hutcheson’s, and sought always to harmonize his philosophical and theological ideas. A political realist unlike Hutcheson, Witherspoon argued that civil society originated both in Locke’s social contract and in Calvin’s religious covenant. He thought that a wide distribution of property was necessary for the public good; that a republic was the best form of government; and that the right of revolution was fundamental. The value and advantage of civil liberty was not that it caused virtuous behaviour or insured individual freedom, but rather that it was useful. Witherspoon elaborated his republicanism in pamphlets, sermons, speeches and other works during the American Revolution. His moral philosophy and theology led him to conclude that the Revolution resulted in the moral regeneration of the American people and the creation of a virtuous, Christian republic.

Wittgenstein, Ludwig Josef Johann (1889-1951)

Ludwig Wittgenstein was born in Vienna on 26 April 1889 and died in Cambridge on 29 April 1951. He spent his childhood and youth in Austria and Germany, studied with Russell in Cambridge from 1911 to 1914 and worked again in Cambridge (with some interruptions) from 1929 to 1947.

His first book, the Tractatus Logico-Philosophicus, was published in 1921. It presents a logical atomist picture of reality and language. The world consists of a vast number of independent facts, each of which is in turn composed of some combination of simple objects. Each object has a distinctive logical shape which fits it to combine only with certain other objects. These objects are named by the basic elements of language. Each name has the same logical shape, and so the same sort of possibilities of combination, as the object it names. An elementary sentence is a combination of names and if it is true it will be a picture of the isomorphic fact formed by the combination of the named objects. Ordinary sentences, however, are misleading in their surface form and need to be analysed before we can see the real complexity implicit in them.

Other important ideas in the Tractatus are that these deep truths about the nature of reality and representation cannot properly be said *but can only be* shown*. Indeed Wittgenstein claimed that pointing to this distinction was central to his book. And he embraced the paradoxical conclusion that most of the Tractatus itself is, strictly, nonsense. He also held that other important things can also be shown but not said, for example, about there being a certain truth in solipsism and about the nature of value. The book is brief and written in a simple and elegant way. It has inspired writers and musicians as well as being a significant influence on logical positivism.*

After the Tractatus Wittgenstein abandoned philosophy until 1929, and when he returned to it he came to think that parts of his earlier thought had been radically mistaken. His later ideas are worked out most fully in the Philosophical Investigations, published in 1953.

One central change is from presenting language as a fixed and timeless framework to presenting it as an aspect of vulnerable and changeable human life. Wittgenstein came to think that the idea that words name simple objects was incoherent, and instead introduced the idea of 'language games'. We teach language to children by training them in practices in which words and actions are interwoven. To understand a word is to know how to use it in the course of the projects of everyday life. We find our ways of classifying things and interacting with them so natural that it may seem to us that they are necessary and that in adopting them we are recognizing the one and only possible conceptual scheme. But if we reflect we discover that we can at least begin to describe alternatives which might be appropriate if certain very general facts about the world were different or if we had different interests.

A further aspect of the change in Wittgenstein's views is the abandonment of solipsism. On the later view there are many selves, aware of and co-operating with each other in their shared world. Wittgenstein explores extensively the nature of our psychological concepts in order to undermine that picture of 'inner' and 'outer' which makes it so difficult for us to get a satisfactory solution to the so-called 'mind-body problem'.

Although there are striking contrasts between the earlier and later views, and Wittgenstein is rightly famous for having developed two markedly different philosophical outlooks, there are also continuities. One of them is Wittgenstein's belief that traditional philosophical puzzles often arise from deeply gripping but misleading pictures of the workings of language. Another is his conviction that philosophical insight is not to be gained by constructing quasi-scientific theories of puzzling phenomena. Rather it is to be achieved, if at all, by seeking to be intellectually honest and so to neutralize the sources of confusion.

1 Life

Wittgenstein was the eighth and last child of a wealthy Austrian industrialist. From 1903-8 he was educated on the assumption that he would be an engineer and in 1908 he came to Manchester to study aeronautics. He continued with this for three years, but at the same time developed his interest in philosophy. He was particularly engaged with logic and the foundations of mathematics, in connection with which he read Frege (§§6-10) and Russell (§§4-11). In October 1911 he gave up engineering and, on Frege's advice, came to Cambridge to study with Russell. In the 1914-18 war he served in the Austro-Hungarian army and during this time completed the *Tractatus Logico-Philosophicus* (1922).

For a time Wittgenstein thought that the *Tractatus* said everything which could be said in philosophy, and so he turned to other things. From 1920 to 1926 he was a schoolteacher in Austria, though this was not a success, since he was severe and demanded too much of his pupils. In 1926-8 he helped to design a house for his sister. In 1927 he resumed philosophical discussion with some members of the Vienna Circle, and in 1929 he returned to Cambridge, lecturing there from 1930 to 1936. From 1936 to 1938 he visited Norway and Ireland, returning to Cambridge in 1938 and being appointed professor there in 1939. He held the chair until 1947, although from 1941 to 1944 he was given leave of absence to work first at Guy's Hospital, London, then at the Royal Victoria Infirmary, Newcastle. After resigning his chair in 1947 he lived in various places, Ireland chief among them, and also visited America.

Wittgenstein impressed those who met him with the power of both his intellect and personality. He had an intense concern for truth and integrity which exerted great attraction, but which also made him difficult to deal with, since he was liable to accuse others of superficiality or dishonesty. He greatly disliked what he perceived as the artificiality and pretentiousness of academic life. His later ideas became known in the 1930s and 1940s through the circulation of copies of *The Blue and Brown Books* (1958) and reports of his lectures, and they acquired considerable influence.

2 Works and method of writing

Throughout his life Wittgenstein wrote down his thoughts in notebooks, returning to the same topics many times, trying to get the most direct and compelling formulation of the ideas. He then made selections and arrangements from these remarks, followed by yet further selection, reworking and rearrangement. The *Tractatus* was the only book published during his lifetime. In 1930 he assembled what we now know as the *Philosophical Remarks*, a work still having much of the outlook of the *Tractatus* and also showing considerable sympathies with verificationism, and in 1932-4 he wrote the *Philosophical Grammar*, in which some central themes of the later philosophy are foreshadowed. But he was not satisfied with either of these, and from 1936 onwards worked on various versions of what we now know as the *Philosophical Investigations* (1953), which he hoped would provide a definitive presentation of his thought. The earlier half of the volume is the part of his work with which he was most nearly satisfied, but he was never fully content with any of it, and in 1949 he abandoned the project of completing it.

The other books we have under his name are all early or intermediate versions of material, left in his papers and edited and published after his death. The *Notebooks* are preliminary versions of ideas which later became the *Tractatus*. *The Blue and Brown Books* were prepared so as to help his students in 1932 and 1933. *Remarks on the Foundations of Mathematics* (1956) contain ideas he worked on from 1937 to 1944 and which he intended at that time to form the second part of the *Investigations* (rather than the psychological topics we now have). From 1944 onwards he worked mainly on philosophical psychology: *Zettel* (1967), *Remarks on the Philosophy of Psychology I and II* (1980) and *Last Writings on Philosophical Psychology I and II* (1982) are from these years. From 1950 to 1951 we also have *On Certainty* (1969) and *Remarks on Colour* (1977). Another source for his views is records of his conversations and lectures taken by friends and pupils.

3 The picture theory of meaning

The *Tractatus* consists of nearly eighty printed pages of numbered remarks. The numbers do not run consecutively but are designed to indicate the relative importance and role of the remarks. There are seven major sentences and each of them (except 7) has subordinate and clarificatory remarks following it, labelled '2.2', '5.4' and so on, down as far as such numbers as '4.0312'.

The topics that preoccupied Wittgenstein when he arrived in Cambridge included the nature of logical truth and Russell's Theory of Types. On both of these matters Russell held that we need an account of very general features of the world and of the kinds of things in it. But Wittgenstein soon came to think that the route to insight was through the contemplation of the nature and presuppositions of individual meaningful sentences such as 'Socrates is wise' and that this contemplation showed Russell's approach to be misguided.

The central fact about such individual sentences is that each says one thing - that Socrates is wise, for example - but is essentially such that it may be either true or false. A false sentence is both out of touch with the world,

inasmuch as it is false, but also in touch with the world, inasmuch as it succeeds in specifying a way that things might be. Wittgenstein holds that all this is possible only because the sentence is complex and has components which represent elements of reality, which exist whether the sentence is true or false and are (potentially) constituents of states of affairs. So, in rough illustration, 'Socrates' represents Socrates and 'is wise' represents wisdom. The truth or falsity of the sentence then depends on whether these elements are or are not assembled into a fact.

Not all sequences of sentence components are acceptable. A mere list of names (for example, 'Socrates Plato') does not hang together as a sentence. And although it looks as if we may apply a predicate to itself (as in '''is in English'' is in English' or '''is wise'' is wise') it seems important to disallow such sequences as truth-evaluable sentences, on pain of falling into Russell's paradox. Russell's account of these matters is that elements of reality come divided into different types - individuals, properties and so on - and that a sentence is to be allowed as meaningful, and so truth-evaluable, only if the elements picked out by the components are of suitably related types.

Wittgenstein maintains, against this, that we do not need rules to bar sentences which would lead to paradox, because when we properly understand the nature of our language we see that we cannot formulate the supposed sentences in the first place. We think we can only because we have misidentified that component in 'Socrates is wise' whose presence in the sentence attributes wisdom to Socrates. This component is not the phrase 'is wise' but the property which the word 'Socrates' has when the words 'is wise' are written to the right of it. To see why this is plausible, consider the fact that there could be a language in which properties are attributed to people by writing their names in different colours. If, for example, we could claim that Socrates is wise only by writing 'Socrates' in red letters then we could never formulate any analogue to '''is wise'' is wise' because we could not take the redness of 'Socrates' and make it red. And although we have given a linguistic role to 'Plato' (as representing Plato) we have not given any role to the property of a name which it acquires when we write 'Plato' to the right of it. That is why a mere list of names does not hang together to make a statement.

Wittgenstein generalizes this idea to claim that the formal properties of any element of the world, that is, the properties which fix its potential for combining into facts with other elements, must be mirrored in the formal properties of the linguistic component which represents it. So the kind of item we call a sentence, and which we often wrongly think to be a complex object, is really a fact. In a sentence certain linguistic components are put together experimentally in a structure which mirrors the formal structure of some possible state of affairs (see Theory of types §1).

4 Negation and tautology

This account does away with the need for a theory of types and Wittgenstein holds that the ideas invoked by Russell to explain the nature of logical truth are similarly unnecessary. His view was that logical truths, such as that all sentences of the form 'p or not p' are true, should be explained by pointing to relations holding between some very abstract kind of logical items - negation, disjunction and the like.

Wittgenstein maintains that the negation sign is not a component of a sentence and so does not represent any element of a possible fact (in the quasi-technical sense of 'component', 'element' and 'represent' introduced above). Rather it is the visible mark of an operation one can perform on a meaningful sentence to produce another sentence. The role of the second sentence is to deny that things are as they would need to be to make the first sentence true.

To see the force of this, we must look again at the account of truth given above. What makes a negative sentence true is not the presence of some 'not-ness' in a fact but rather the absence of that (the combination of elements) which would have made the unnegated sentence true. This is similarly the case with the other so-called logical constants. Thus 'or' does not stand for a possible element in a fact but is a sign by which one can correctly link two sentences if the components of either are so combined as to yield a truth.

Logical tautologies thus do not reveal the nature of special logical objects. Such sentences as 'It is raining or it is not raining' do not say anything. But their possibility is a corollary of the existence of a language adequate to say the kind of thing which can be said. So contemplating them can draw our attention to the logical structure of the world (see Logical constants; Logical form; Logical laws).

5 Simples

The ideas outlined in the last two sections are already present in the sets of notes which Wittgenstein wrote in late-1913 and 1914. But the *Tractatus* in its complete form incorporated several further important ideas. One of these, perhaps adopted from Frege, is the view that sense must be determinate, that is, that every meaningful sentence must be either true or false in every possible state of affairs. But Wittgenstein differs from Frege in thinking that ordinary language, although misleading in surface form, is in order, and so already fulfils this condition of determinacy.

Determinacy entails that there must be 'objects', that is, utterly simple, eternal and unalterable elements, out of which all facts are composed. Moreover the links between our language system and reality must be set in place at this basic level. Suppose that language-world links were set up so as to connect a basic linguistic component with some element of reality which was not basic. The existence of this element would be contingent and would depend upon some simpler elements being suitably combined in a fact. A sentence containing this imagined basic component is clearly not true in a world where the simpler elements are not suitably combined. But it is equally unhappy to say that it is false, because the component itself does not specify what the simpler elements are or that they must be combined, and so it is no part of its meaning that their failure to be combined is relevant to its falsehood. To insist on the undefinability of this imagined basic element of language is to insist that it has meaning only through its connection with the item it represents. So in a world lacking that item it has no meaning, and sentences containing it are neither true nor false. But this, given the assumption of determinacy of sense, is a *reductio ad absurdum* of the idea that meaning can be conferred in this imagined way.

We may have an apparently basic sentence component which is linked to a contingently existing item (for example 'Socrates' as a name of Socrates). But this is only possible because a definition of that component can be given in our language system. The link between Socrates and his name is thus not a basic point of attachment between language and the world (contrary to the impression given in our earlier rough and ready example). It is a consequence of these ideas that there must be a complete analysis of every sentence of our language into a truth-functional combination of elementary propositions, the components of which are simple signs representing objects.

But what are these simple objects? Wittgenstein, like Russell but unlike Frege, does not allow for any contrast between sense and reference within the meaning possessed by names of simples. This puts one demand on simples: they cannot be items with distinguishable aspects, that is, items which can be conceived of in several logically distinct ways. If they were, then there would also be the possibility of one name for a simple as conceived one way and another non-synonymous name for it as conceived another way - contrary to the denial of the sense-reference distinction. So a simple is the kind of thing which, if apprehended in such a way that it can be named, is apprehended exactly as it is in its entirety.

In so far as Wittgenstein drops any hints, it is that simples are phenomenally presented items, such as points in the sensory field and the properties they have, for example, shades of experienced colour. But he cannot give this answer officially because to do so would clash with another of the themes brought to prominence in the later development of the *Tractatus*. This is the claim that all necessity is logical necessity, and hence would be revealed as tautological in a complete analysis (see §7 below). A corollary of this is that all atomic facts are independent of each other and no elementary sentence can entail or be the contrary of any other. Such things as colours cannot then be 'objects' because attribution of different colours to one thing, as in 'a is red' and 'a is green', produces sentences which are contraries.

The topics so far discussed are treated primarily in the remarks following the main sentences numbered 2, 3 and 4. The remarks following 5 and 6 deal mainly with implications of this atomist conception for certain issues in logic (generality and identity for example) and for the nature of science, mathematics and statements of probability. On the last mentioned subject, Wittgenstein's brief remarks are one important source for the approach later developed by Rudolf Carnap (see Carnap, R. §5; Logical atomism §1).

6 Thought, self and value

Wittgenstein writes, 'There is no such thing as the subject that thinks or entertains ideas' (5.631). His grounds for

this are similar to those of Hume, namely that a unified, conscious self cannot be an element in any encountered fact. Hence no such item can be among those objects represented in thought. So reports of the form ‘A believes that p’, which seem to mention such a subject, are really of the form ‘"p’’ says that p’. They report the existence of a sentential complex, the components of which are correlated with the elements of the potential fact that p. There are then no selves in the world but, at best, bundles of sentence-like items.

But Wittgenstein also says ‘What the solipsist means is quite correct; only it cannot be said but makes itself manifest’ (5.62), and ‘The subject does not belong to the world: rather, it is a limit of the world’ (5.632). One interpretation connects these remarks with the idea of projection - he speaks of using a propositional sign as a projection of a possible situation by thinking out its sense. The picture suggested is that of a subject who is the origin of the lines of projection which link representing items with what they represent and whose existence is thus presupposed by their meaningfulness. ‘The world is *my* world: this is manifest in the fact that the limits of *language* (of that language which alone I understand) mean the limit of *my* world’ (5.62). So perhaps Wittgenstein’s idea is that the existence of a unique self (me) at the limit of the world is shown by the existence of representations which are meaningful to me.

Wittgenstein also offers, in the closing pages of the *Tractatus*, a number of gnomic remarks about value, death and the mystical, among them that no value exists in the world, that ethics cannot be put into words, that the will as a subject of ethical attributes cannot alter facts but only the limits of the world, that at death the world does not alter but comes to an end, that feeling the world as a limited whole is the mystical and that the solution of the problem of life is seen in the vanishing of the problem. These claims are to some extent intelligibly grounded in ideas concerning the self and what can be said. But they also represent a leap of development beyond those, a leap which comes in part from Wittgenstein’s experiences in the First World War and the religious convictions to which his always intense and serious outlook then led him.

7 Saying and showing

Wittgenstein thought that by reading the *Tractatus* one might come to grasp certain things about the nature of meaning, reality and value, among them the kinds of things outlined above. But he also held that these things could not be *said* but only *shown*, and the attempt to say them ends up producing nonsense. Most of the *Tractatus* itself is thus nonsense. This claim is highly paradoxical and may seem to be unnecessary and grandiose mysticism, especially when viewed as part of the same package as the difficult remarks about the will and solipsism. But this is unfair. In many of its applications, the claim is well motivated, given the picture theory of meaning.

Most of the linguistic manoeuvres which Wittgenstein condemns as nonsensical are attempts to say things which are both necessary but also substantive - that is, not mere tautologies. Thus they include moves to assign elements of reality or language to their logical types (‘Socrates is a particular’), related attempts to describe the logical forms of sentences or facts and also efforts to list the simples. (Claims about what is valuable could also have this status of seeming to be both substantial and necessary.) But if the picture theory of meaning holds in complete generality there cannot be such statable necessary truths. To say, for example, that object b is F we require that there be a linguistic representative of b (‘b’) and one of F-ness (the property of having ‘F’ to the right) which can be combined or not, just as b and F-ness can be combined or not. There must be complexity and there must therefore be the possibility of dissociation as well as association. But if b and F-ness necessarily go together (for example, Socrates must be a particular) then b cannot be dissociated from F-ness and it is a confusion to imagine that its being F is a fact with a composite structure. Hence it is also a confusion to imagine that it is something of the kind which can be said, on the account of saying which is offered by the picture theory.

8 Transition

In the *Tractatus* Wittgenstein took a lofty tone about simple objects; he had proved that they existed and it was of no importance that we cannot say what they are. But in the first years of his return to philosophy in 1927-31 one thing which occupied his attention was the detailed workings of various parts of our language, notably those involved in talking of shape, length and colour and other observable properties of items around us. His aim in considering them was to fill in that earlier gap by giving an account of the fundamental features of both language and the world.

He soon became convinced that the idea of independent elementary propositions was indefensible. For example, the incompatibility of 'a is red' and 'a is green' cannot be explained (contrary to what he had urged in the *Tractatus*) by analysing the two propositions and showing that one contains some elementary proposition which contradicts an elementary proposition in the analysis of the other. Rather the whole collection of colour judgments come as one set, as the marks along the edge of a ruler come as a set. To measure an object we hold a ruler with its marks against the object, that is, in effect we hold up a whole set of possible judgments of length, and we read off which is correct; to see that one judgment is correct is to see at the same time that all the others are incorrect. Something similar holds for colour and for many other concepts, except that in these cases the 'ruler' is not physically present. The differences between concepts have to do with the logical shapes of their 'rulers' and with the different methods by which they are compared to reality.

Other topics which occupied Wittgenstein at this time were those of psychological phenomena and the use of the word 'I'. And he also worked extensively on the nature of mathematics. Ideas in common with those of the logical positivists are apparent in some of the writings of this time. Indeed the slogan known as the verification principle - 'the meaning of a proposition is its method of verification' - may have originated with Wittgenstein. But he found it impossible to accept this as a clear statement which could provide one of the starting points for elaborating a philosophical system. He was aware of further puzzles and was temperamentally incapable of putting them on one side for the purpose of building an intellectual construct which might be based on misapprehension and which failed to address questions which still perplexed him (see Logical positivism §§3-4; Vienna Circle §2).

9 Dismantling the *Tractatus* picture

Paragraphs 1-242 of the *Philosophical Investigations* (roughly the first third of the book) are generally agreed to provide the most focused presentation of some of the central ideas of Wittgenstein's later outlook, in the context of which his views on philosophy of mind, mathematics and epistemology can helpfully be seen. We may divide the paragraphs into three groups: §§1-88 raise a variety of interrelated difficulties for the outlook of the *Tractatus*, §§89-142 discuss the nature of logic, philosophy and truth, and §§143-242 contain the so-called rule-following considerations.

The first group has two main targets: first, the idea that most words have meaning in virtue of naming something and, second, the idea that meaning requires determinacy and so exactness. Against the former Wittgenstein points out that different words function in different ways. To understand 'five', for example, a person needs to be able to count and behave appropriately on the result of a counting; to understand a colour term might, by contrast, involve knowing how to compare the specimen to be judged with a sheet of samples. To teach language one must train a person to produce and respond to words in the context of everyday activities such as fetching things, measuring, building, buying and selling. We can throw light on meaning by reflecting on simple 'language games', involving such integration of speech and action. To say that every word names something is like saying that every tool in the tool box modifies something. We can describe things this way if we insist: 'The saw modifies the shape of the board; the ruler modifies our knowledge of a thing's length'. But such assimilation may lead us to overlook important variety rather than representing a useful insight. To get someone to understand a word it is not enough to bring them face-to-face with the supposed referent while repeating the word. In order to profit from the confrontation, the learner must know what kind of word is being taught (for a number, shape, colour, and so on). And this in turn involves already being at home with the everyday activities into which remarks using the word are woven. 'For a *large* class of cases - though not for all - in which we employ the word ''meaning'' it can be defined thus: the meaning of a word is its use in the language' (1953: §43).

On the second topic Wittgenstein remarks that drawing a contrast between 'simple' and 'complex' depends upon context and interest. Items which might be seen as complex in one context could be taken as simple in another and vice versa. So the related notion of exactness is also context-relative. A word does not become unusable and hence meaningless because its use is not everywhere bounded by rules. That we can imagine circumstances in which a given description would seem inappropriately vague or in which we would not know whether to say that it was true or false is no criticism of its current use and hence no argument that it does not have meaning. Hence the idea that every meaningful sentence must have some underlying analysis in terms of simples is mistaken.

Each sort of word is at home in its own language game. But there are not always clear-cut relations of subordination or dependence between different language games. There are many predicates (for example,

‘intention’, ‘thought’, ‘statement’, ‘number’, ‘game’) which clearly do not name simples, because they have interesting richness and apply to complex items. But it is not the case that such predicates must have an analysis in terms of ‘simpler’ predicates. Search for such an analysis may reveal instead a ‘family resemblance’. Persons who recognizably belong to the same family may have various resemblances, of build, features, colour of eyes, gait, temperament and so on, which ‘form a complicated network of similarities, overlapping and criss-crossing’ (1953: §66), without one set of such resemblances being necessary and sufficient for having the appearance of a member of that family.

On the basis of this survey of the actual workings of language, Wittgenstein then concludes that the *Tractatus* picture of a detailed crystalline structure present in both world and language is an illusion.

But perhaps the considerations outlined require only minor tinkering with the *Tractatus* picture? We might say: ‘Certainly linguistic representations of states of affairs are put to various uses, in commands, jokes, stories etc., as well as in straight reports; also what degree of exactness we need is fixed by context; hence we should accept that for many practical purposes vague remarks are adequate. But none of this shows that we must discard the *Tractatus* picture of a fully determinate world, structured by simples; nor does it show that the idea of constructing a complete and exhaustive description of it need be abandoned. All it shows is that our everyday language mirrors the world less accurately than an imaginable ideal scientific language.’ That such a reading is inadequate is shown by considering the remarks on rule-following found in paragraphs 143-242.

10 Rule-following

By ‘rule’ Wittgenstein does not mean an abstract standard according to which some act may be judged right or wrong. Rather he means a concrete item, such as a noise, mark or gesture, which is presented to a person and by attending to which they direct their behaviour, the link between rule and response being learned and conventional. An enormous number of human activities can be seen as instances of rule-following. The activities include imitating the gestures and noises which others make, copying shapes, converting marks into noises as in reading music, chanting the number sounds in sequence, and so on. More generally, both nonverbal behaviour in response to verbal instruction (fetching a book when told to do so) and also producing linguistic reports (where the world itself is the guide and the utterance is the response) may be described as rule-following. Rule-following is thus at the heart of linguistic competence. If we further accept that coming to use a rich and expressive language is an indispensable part of coming to grasp complex concepts and to make reflective judgments, then rule-following is also at the heart of our lives as thinking creatures.

It is generally agreed that Wittgenstein has telling negative points to make about one attractive but misleading picture of rule-following. On this picture, to understand a rule, for example, to grasp what is meant by ‘Add two’, it is necessary and sufficient to have a certain sort of item, an image, feeling or formula, occur in the mind when the instruction is heard. For example, having a mental image of two blocks appearing at the end of a line of blocks is the sort of thing which might be imagined to constitute understanding ‘Add two’. This image is supposed to do two things. First, it helps bring about that the person goes on to produce a particular response, for example, saying ‘Eight’ if the previously given number was six; second, it sets a standard by which that response can be judged correct or incorrect.

But the picture will not do. A person might have such an image while responding to ‘Add two’ as if it meant ‘Multiply by two’. Moreover the person’s behaviour (the regular patterns of action, what seems to be regarded as a mistake, and so on) could show that for them, ‘Add two’ actually means ‘Multiply by two’. So images guarantee neither subsequent behaviour nor the appropriateness of a particular standard of assessment.

What the case makes us see is that an image, feeling or formula is merely another rule-like object (that is, a potential vehicle of meaning) rather than the meaning itself. An item is not automatically a self-interpreting sign, that is, one which fixes and enforces a certain reading of itself, simply in virtue of existing in the mind rather than in the outer public world. So images and the like are not sufficient for understanding; but neither are they necessary, since in many cases they do not occur. Typically when someone responds to everyday and familiar language they just act unhesitatingly and spontaneously, without consulting any inner item.

To teach someone to follow a rule, for example, to understand ‘Add two’, we put them through a finite amount of training, primarily by working through examples of adding two. These examples may appear to be another

resource for pinning down meaning. But being only finite in number, they are bound to have more than one feature in common. Thus they do not themselves determine a unique interpretation for the sign we associate with them. A learner might exhibit a future bizarre divergence from what is expected, for instance by saying that adding two to 1000 yields 1004. And if this occurred it would suggest that they had all along been struck by some feature other than the one intended.

The central point here is that, for there to be meaning, the rule-followers must have fixed on one rather than another of the various similarities between the teaching examples and have associated it with the rule, that is, with the mark or sign to which they respond. ‘The use of the word ‘‘rule’’ and the use of the word ‘‘same’’ are interwoven’ (1953: §224). But neither the examples nor the rule itself determine which similarity this is; and imagined inner surrogates, in which we would like to see the relevant resemblance encapsulated, turn out to be equally inefficacious.

These reflections do not just undermine one picture of the psychology of understanding. They are also relevant to the metaphysics of the *Tractatus*. If the world consisted of intrinsically articulated facts as envisaged in the *Tractatus*, then there would exist items, namely the simple objects, which would fix the one and only absolute standard of similarity. If there is a simple which is a common element in two separate facts then there is a basic real resemblance between those facts; if not, not. Every other real resemblance which can be meaningfully labelled, for example, by the predicates of everyday language or science, must be founded in simples. A putative linguistic expression which is not tied to some definite combination of simples is, on the *Tractatus* view, an expression without meaning which is merely randomly applied. Further, as we saw earlier, a simple is the kind of thing which, when apprehended, must be apprehended as it is. So representing a simple, whether by a direct cognition of it or by having in mind something which encapsulates its nature, is to be aware of a self-interpreting item, something which dictates what is to count as ‘the same’. But this sort of confrontation is what the rule-following considerations suggest to be unintelligible.

Thus the discussions of §§143-242 can be seen as interweaving with and reinforcing those of §§1-88. The whole undermines not only the idea of closeness of fit between a *Tractatus* world and everyday language, but the underlying conception of that world itself, namely as already determinately articulated into facts by simples which we can apprehend (see Meaning and rule-following §§1-2).

11 The later picture of meaning

The *Tractatus* view offers us a world articulated of its own nature into value-free facts which are the subject matter of the natural sciences together with a mind confronting that world and attempting to mirror it in its thoughts. It also tells us that there is only one self and that it is an item at the limit of the world which cannot act responsibly in the world.

However attractive the first element here, everyone would agree that there is something seriously wrong with the solipsism of the second. So one essential move in amendment is to make the self responsibly active, to bring it in from the limit and to locate it firmly in the world, together with other selves. We may do this while leaving in place the idea of the world as the totality of value-free facts. Then the self which appears in the world must be some subset of such facts. This yields an extremely powerful and attractive overall picture. But it also generates many philosophical puzzles, those to do, for example, with giving naturalistic accounts of consciousness, free will, rationality and so on.

This overall picture cannot be Wittgenstein’s, however, if §10 is right in its reading of the rule-following considerations. The idea of an independently articulated world is not acceptable to him. We cannot understand our concepts by pointing to simples in the world which force them on us. To understand meaning we must look to use, at how our actions and concepts are interwoven. The fact that makes a sentence true is grasped through seeing when the sentence is correctly used, and that in turn is grasped only by seeing the full shape of the language games in which it is used. For a concept to be truly applicable to the world, and so for its corresponding property to have instances, is not for it to pick out some simple which is among the timelessly given building-blocks of all worlds. Rather it is for the life of which use of that concept is a part to be liveable in this world. Wittgenstein thus moves from a bold and simple form of the correspondence theory of truth in the *Tractatus* to a redundancy theory in the *Investigations*.

The self need not, on this view, be an assemblage of value-free facts. It is rather a locus of abilities, a person who can be trained to follow rules, to use and respond to language, in the way normal humans can. And since concepts are aspects of our way of life rather than items forced on us by the world, understanding what it is to have a particular concept involves 'assembling reminders' about how it works for us and how our various activities and ways of talking build together into our way of life.

If it is correct to conceive of understanding as an ability, then the exercise of this ability in everyday situations will often be just some confident, spontaneous action or utterance, which the subject will not be able to justify by pointing to something, other than the situation or words responded to, which guided them.

> 'How am I able to obey a rule?' - if this is not a question about causes, then it is about the justification for my following the rule in the way I do. If I have exhausted the justification I have reached bedrock and my spade is turned. Then I am inclined to say: 'This is simply what I do'.
>
> (1953: §217)

But this need not worry us. 'To use a word without justification does not mean to use it without right' (1953: §289). The fact is that we do find such confident and unhesitating responses in ourselves. Also we (usually) agree with others; and where we do not we (usually) agree on how to settle the dispute. So we have no reason to doubt that in general we do indeed mean what we take ourselves to mean.

Indeed we can put things more strongly than this. It is not just that it is sensible, practically speaking, for me to make a leap of faith and decide to carry on as if I and others mean what it seems we mean. We have no more choice about this than we do about taking 'Eight' to be the right response to 'Add two to six'. The language game of ascribing meanings to the remarks of ourselves and others is as central and indispensable to a recognizably human life as anything in our linguistic repertoire. Moreover the rich and complex social world in which we find ourselves sustains our practice of so doing. So we and our meanings are just as much part of the world as the stars, rocks and trees around us. And since we are no longer committed to the idea of one totality of facts, those of value-free natural science, this recognition does not now produce cramps or pressures to reductive manoeuvres (see Private states and language §4).

12 Alternative readings

The account of §§9-11 presents Wittgenstein as inviting us to abandon the idea of our meanings and judgments being securely moored to something outside us which imposes itself on us and keeps us in line. We are to become aware of our involvement in and responsibility for our own judgments and the way of life of which they are part. We are also to acknowledge that we cannot prove the unique correctness of our way of life and its associated concepts. (The arguments of the *Investigations* against the position of the *Tractatus* thus have much in common with themes explored by other late-nineteenth-century and twentieth-century thinkers, such as Nietzsche, William James, Heidegger, Quine and Derrida (see Nietzsche, F. §6; Heidegger, M. §§2-4; Quine, W.V. §5).) But, the reading given in §11 implicitly suggests, this need not lead us to scepticism about the notions of meaning, fact, objectivity or truth.

This interpretation, although not idiosyncratic, is by no means generally accepted. There are a large number of differing construals of Wittgenstein's overall intention, many of which have in common that they present the consequences of abandoning the *Tractatus* view as more radical and/or more deflationary, than is suggested in §11.

One interpretation stresses a contrast between the *Tractatus* and the later writings which is different from any highlighted earlier. It takes the rule-following considerations to show that we cannot make sense of grasp of meaning which fixes truth conditions independent of our ability to verify that they obtain. The later Wittgenstein is thought to insist (as against his earlier self) that all meaning be explicated by appeal to assertibility conditions rather than such possibly verification-transcendent truth conditions and he is recruited onto the antirealist side of the debate in the dispute between realism and antirealism.

Another much discussed view is presented by Saul Kripke. If there were facts about meaning, he argues, they would have to be constituted by something about past behaviour or present occurrences in the mind. So §§143-242 can be read as showing that there are no facts about meaning. Our practice of labelling remarks 'correct' or

'incorrect' and ascribing 'meanings' to them has a role in our social life. But such linguistic moves do not have truth conditions. Instead they have only appropriateness conditions. We are licensed to make them when others in our community keep in step with us in certain ways in their patterns of utterance.

Yet a third interpretation takes it that Wittgenstein espouses relativism. One response to the idea that there are no simples is to take it that the world is a featureless mush or unknowable something. Any apparent structure in it is then imposed by us. Hence the familiar physical and social world we experience is a creation of ours. But there are several possible but incompatible ways of imposing structure, one of which we are physiologically and/or socially caused to adopt. So no judgment can claim to be 'true' in a non-relative sense; at best it can be 'true for us'.

One interesting issue in assessing this view is what status Wittgenstein intended for the sketched alternative ways of responding to language teaching. Certainly they need enough feasibility to dislodge the idea of the one and only enforced way of dividing up the world. On the other hand it is not clear that he takes us to be entitled to assert that there are conceptual schemes which are both incompatible with ours and also fully possible.

Many other readings are also possible, detecting in his writings elements of pragmatism, behaviourism and even deconstructionism (see Behaviourism, analytic; Deconstruction; Pragmatism §2; Realism and antirealism §4; Relativism).

13 Philosophy of mind

The *Tractatus* picture of the relation of language to its subject matter is especially attractive in the case of psychological notions. A sensation such as pain is easily conceived as a phenomenon which impresses its nature and identity conditions on one who has it, independent of external circumstances or bodily behaviour. The private language argument (§§243-71) examines this idea in the light of the earlier discussion of meaning. One aim is to show that our actual use of terms for sensations does not and could not conform to the pattern suggested.

The rule-following considerations suggest that no standard for what is to count as 'the same' can be fixed merely by uttering a word to oneself while being vividly aware of what one experiences. For one kind of item rather than another to come into focus out of the indefinite variety potentially presented in an experience, that experience must be embedded in one kind of life rather than another. Relatedly, for a word to have meaning there must be some extended practice in which its use has a point. This is as true of sensation words as of any others. We teach and use them in a complex setting of physical circumstances and expressive bodily behaviour. This setting, says Wittgenstein, is not externally and contingently linked to sensation but is an integral part of the sort of life in which the general category 'sensation' makes sense and in which particular sensations can be individuated.

Wittgenstein considers many other topics in philosophical psychology, among them intention, expectation, calculating in the head, belief, dreaming and aspect perception. A constant theme is the need to counter the attraction of the model of name and object, which (together with such things as the special authority which each person has to pronounce on their own psychological states) leads us to conceive of the 'inner' as a special mysterious realm, distinct from the 'outer' or physical. He offers such general remarks as 'An ''inner process'' stands in need of outward criteria' (1953: §580). He also returns repeatedly to the idea that authoritative first-person psychological claims should be seen as expressions or avowals of those states which we are inclined to insist that they describe. These sorts of moves have led to the idea that he denies the existence of the 'inner' and is really a behaviourist.

He was aware of the risk of this reading:

> 'But you will surely admit that there is a difference between pain-behaviour accompanied by pain and pain-behaviour without any pain?' - Admit it? What greater difference could there be? - 'And yet you again and again reach the conclusion that the sensation itself is a *nothing*.' Not at all. It is not a *something*, but not a *nothing* either!
>
> (1953: §304)

Thoughts and experiences are, on his view, necessarily linked to expressive behaviour. 'Only of a living human being and what resembles (behaves like) a living human being can one say: it has sensations; it sees; is blind; hears; is deaf; is conscious or unconscious' (1953: §281). But this does not mean that any reduction of the mental

to the behavioural is possible or that the psychological is not real. To see Wittgenstein's view sympathetically it is important to keep in mind the upshot of §§1-242. There is no a priori guarantee of some privileged set of classifications (for instance, those of natural science) in terms of which all others must be explained. To understand any phenomenon we must get a clear view of the language games in which terms for it are used; and the logical shapes of these may be very different from those which are initially suggested by the pictures which grip us (see Private language argument §§1-3).

14 Philosophy of mathematics

Platonism in mathematics involves two claims, that there is a realm of necessary facts independent of human thought and that these facts may outrun our ability to get access to them by proofs. Platonism is attractive because it accounts for several striking features of mathematical experience: first that proofs are compelling and yet may have conclusions which are surprising, and second that we seem to be able to understand some mathematical propositions without having any guarantee that proofs of them exist.

Wittgenstein never accepted Platonism because he always took the view that making substantive statements is one thing, while articulating the rules for making them is another. So-called necessary truths clearly do present rules of language, inasmuch as accepting them commits one to allowing and disallowing certain linguistic moves. Wittgenstein holds that it is therefore a muddle to think that such formulations describe some particularly hard and immovable states of affairs. Thus in the *Tractatus* mathematical propositions are treated together with tautologies as sets of signs which say nothing, but show the logic of the world.

Nevertheless the *Tractatus* view has some kind of affinity with at least the first claim in Platonism, inasmuch as the rules of our language are taken to reflect some logical structure independent of us. But when Wittgenstein comes to see linguistic rules as features internal to our practices, the resulting picture is unwelcoming even to this. There is now no such thing as 'the logic of the world', whether to be shown or said. Instead, in *Remarks on the Foundations of Mathematics*, he explores ideas of the following kinds.

At a given time we have linguistic practices directed by certain rules. Someone may now produce a proof of a formula which if accepted would be a new rule - for example, '$14 + 3 = 17$'. It is natural to think that to accept this is to unpack what we were already committed to by our understanding of '17', '+', and so on. But the rule-following considerations unsettle this assumption because they undermine the idea of an intellectual confrontation with an abstract item which forces awareness of its nature upon us and they also bring to our attention the element of spontaneity in any new application of a given term. Rather to accept the proof and its outcome is to change our practices of applying signs like '17', because it is to adopt a new criterion for judging that seventeen things are present, namely that there are two groups of fourteen and three. Hence to accept the proof is to alter our concepts. What makes mathematics possible is that we nearly all agree in our reaction to proofs, and in finding them compelling. But to seek to explain this by pointing to Platonic structures is to fall back into incoherent mythology.

My own view is that it is persistent uneasiness with the first claim in Platonism which primarily motivates Wittgenstein's reflections on mathematics. But those who see him as an antirealist will put more stress on hostility to the second claim (the idea of verification transcendence) and certainly some of Wittgenstein's remarks (for example, his suspicion of the application of the law of excluded middle to mathematical propositions) have affinities with ideas in intuitionistic logic. A third reading will bring out the conventionalist-sounding elements, on which we choose what linguistic rules to adopt on pragmatic grounds.

In addition to reflections on the nature and use of elementary arithmetical claims, Wittgenstein also applies his ideas to some more complex constructs in mathematical logic, such as the Frege-Russell project of deriving mathematics from logic, Cantor's diagonal argument to the non-denumerability of the real numbers, consistency proofs and Gödel's theorem. His general line here is not that there is anything wrong with the mathematics but that the results have been misconstrued, because they have been interpreted against a mistaken background Platonism. Some mathematical logicians claim that Wittgenstein has not understood properly what he is discussing. His views on consistency and Gödel in particular have aroused annoyance (see Antirealism in the philosophy of mathematics §2; Intuitionism; Realism in the philosophy of mathematics §2).

15 Ethics, aesthetics and philosophy of religion

In the *Tractatus* Wittgenstein consigns ethics to the realm of the unsayable, and he takes the same line in his ‘Lecture on Ethics’ ([1929] 1993). Here he says that ethics (which he links to aesthetics and religion) arises from a tendency in the human mind to try to express in words something - roughly the existence and nature of absolute value - which seems to manifest itself to us in certain experiences. (He gives as an instance the experience of finding the existence of the world miraculous.) It is essential to this impulse that it seeks to go beyond the world and significant language; so it is bound to issue in utterances which are nonsensical. Nevertheless, he says, he has the greatest respect for this impulse and would not for his life ridicule it.

This position resembles the emotivism associated with logical positivism in distinguishing ethical utterances sharply from those of science (that is, those which are capable of rational assessment, and can be true or false). But it also differs from it in being, in spirit, an ethical realism, albeit of a mystical kind.

In his later writing he rethought his views on meaning, mathematics and the mind but did not return to any sustained discussion of ethics or aesthetics (although there are scattered remarks, particularly on the aesthetics of music, in *Culture and Value* (1980)). One interpretation of the later outlook, however, provides a hospitable setting for an ethical realism of a less mysterious kind, one which allows for the statement and rational discussion of truth-evaluable ethical claims. Philosophers of meta-ethics taking themselves to be working within a Wittgensteinian outlook have urged that our inclination to insist on a dichotomy between fact and value, or between cognition and feeling, should be resisted, as the outcome of the grip on us of some misapplied picture. Moreover Wittgenstein’s emphasis on attention to the actual workings of language could encourage a distinctive approach to first order ethical questions (see Wittgensteinian ethics §2). But he himself never developed this, nor does he engage with issues in political philosophy.

The later outlook enjoins us to study each distinctive area of language as far as possible without preconceptions. If we do this for religious language, Wittgenstein holds, we shall see that religion is not a kind of science and hence is not open to criticism on the grounds that, as science, it is unconvincing (see, for example, ‘Remarks on Frazer’s *Golden Bough*’ ([1931] 1993)). Some take it that this implies that no religious utterance can be properly subject to any criticism other than that coming from inside the same religious community or tradition.

16 Epistemology

One familiar traditional philosophical problem is that of scepticism, that is, whether we can rightly claim to know such things as that physical objects exist independent of our perception, that the world was not created five minutes ago and so forth.

Wittgenstein’s most extended discussion of these issues is in *On Certainty* (1969). He starts from the kinds of examples invoked by G.E. Moore in his attempt to combat scepticism, such as ‘Here is a hand’ and ‘The Earth has existed for a long time before my birth’ (see Moore, G.E. §§3-4). Moore is wrong, Wittgenstein thinks, in taking it that we are plainly entitled to assert that we know these things. But Moore is right in thinking that the claims form an interesting class. It is impossible to conduct life and thought without taking some things entirely for granted, and the propositions Moore identifies are the articulated forms of things which play this role for us. They help to define our world picture and underpin the procedures by which other claims (ones that are in fact doubted and tested) can be assessed. But they cannot themselves be assessed because there is nothing relatively more certain by which we can get leverage on them. Someone who seems to doubt them is thought mad and, from a first-person point of view, when I imagine doubting such things I contemplate a situation in which I would no longer know how to reason about anything. There are close links between these themes and the idea that the workability of any language game presupposes certain very general facts of nature.

The relevance of this for the traditional question of scepticism is that it is, in its form, misconceived. The central use of ‘know’ is in connection with propositions where testing is possible. Hence one who uses it in connection with the propositions which help define our worldview (as is in fact done only in philosophy and not in ordinary life) has extended the word to a situation where procedures do not exist for assessing either the first-order claim or the claim to knowledge of it. This is not to say that the word ‘know’ is unintelligibly and wrongly used in the philosophical debate. We can sympathize with the sceptical impulse, which springs from awareness of the fact that our language games are not based on grounds which compel us to them or guarantee their continued success. But

we can also sympathize with the anti-sceptical position which insists that acceptance of these central propositions underpins our being able to do any thinking at all, so that claims to doubt them are empty (see Scepticism).

17 Wittgenstein's conception of philosophy

In two central respects Wittgenstein stands squarely within the main historical tradition of philosophy, first in the nature of the issues which excited and intrigued him intellectually - meaning, the self, consciousness, necessity - and second (going back to the roots of the tradition) in his being a 'lover of wisdom', that is, one who is seriously concerned about having a right stance to the world both intellectually and practically and who is committed to the use of the intellect (among other things) in helping to achieve this.

But he differs from many philosophers in his conviction that a great number of traditional philosophical problems are the result of some deep kind of muddle, and in his belief that the answers given and the way they are debated hinder rather than help us in achieving wisdom. This conviction gripped him from very early on and philosophical thought therefore presented itself to him as a tormentingly difficult struggle to be honest and to free himself from misleading preconceptions.

So the word 'philosophy' has, in all his writings, two uses. On one it describes a body of confused utterances and arguments, arising largely from misunderstanding of the workings of language, and on the other it describes an activity of helping people to get free of the muddles. Another important continuity is his insistence that there cannot be philosophical theories and that the helpful activity of philosophy ought only to consist of making uncontentious statements, of describing and assembling reminders. In the context of the picture theory of meaning, this is comprehensible (see §7). But it is less clear that it is required by the later view.

In part Wittgenstein is here stressing that we cannot have the kind of explanation of our concepts which the *Tractatus* picture seemed to promise. Our form of life cannot be grounded but only described and lived. In part he is questioning the impulse to look for quasi-scientific theories of the nature of philosophically puzzling phenomena. But these two interrelated points do not obviously add up to a complete embargo on anything which could be called 'philosophical theory'. It is in the spirit of the later philosophy to point out that there are many different kinds of things which can be called 'theories'. Everyone engaged in reflection on the topics Wittgenstein considers (including Wittgenstein himself) finds it natural to articulate in words the states they arrive at and to engage with these words and those of others in the mode of further comment and assessment.

We become aware here, and at many other places, of the open-ended and unfinished nature of Wittgenstein's reflections. His writings have aroused great devotion because of the honesty and depth which many find in them. But it is important not to treat them with superstitious reverence. Rather they should be read in the spirit in which he intended, namely as an invitation to explore with as much integrity as possible one's own perplexities and what would resolve them.

JANE HEAL

List of works

Wittgenstein, L.J.J. (1922) *Tractatus Logico-Philosophicus*, trans. C.K. Ogden and F.P. Ramsey, London: Routledge; trans. D.F. Pears and B.F. McGuinness, London: Routledge, 1961.(The major work of Wittgenstein's early period and the only book published during his lifetime. The first English translation was revised and approved by Wittgenstein himself, though the later version is now standard. The German version was published in 1921 in *Annalen der Naturphilosophie*.)

Wittgenstein, L.J.J. (1953) *Philosophical Investigations*, ed. G.E.M. Anscombe and R. Rhees, trans. G.E.M. Anscombe, Oxford: Blackwell.(The most polished and worked over of all Wittgenstein's later work; it contains the presentation of his ideas on meaning and philosophical psychology with which he was most nearly satisfied.)

Wittgenstein, L.J.J. (1956) *Remarks on the Foundations of Mathematics*, ed. G.H. von Wright, R. Rhees and G.E.M. Anscombe, trans. G.E.M. Anscombe, Oxford: Blackwell, 3rd edn, 1978.(Selections from Wittgenstein's notebooks and manuscripts from 1937 to 1944. The third edition contains a larger selection of material than the first edition.)

Wittgenstein, L.J.J. (1958) *The Blue and Brown Books*, Oxford: Blackwell.(These were dictated to his pupils in

1933-5 and are among the few works composed by Wittgenstein in English. A good way of approaching his later thought.)

Wittgenstein, L.J.J. (1961) *Notebooks 1914-16*, ed. G.H. von Wright and G.E.M. Anscombe, trans. G.E.M. Anscombe, Oxford: Blackwell.(Helpful for understanding the *Tractatus*, since it contains what is left of the preliminary writings of that period.)

Wittgenstein, L.J.J. (1967) *Zettel*, ed. G.E.M. Anscombe and G.H. von Wright, trans. G.E.M. Anscombe, Oxford: Blackwell.(A selection, made by Wittgenstein himself, of remarks that he wrote mainly between 1945 and 1948.)

Wittgenstein, L.J.J. (1969) *On Certainty*, ed. G.E.M. Anscombe and G.H. von Wright, trans. D. Paul and G.E.M. Anscombe, Oxford: Blackwell.(A collection of all the material on knowledge and certainty from the last year and a half of Wittgenstein's life, where he treated the topics at length at several points in his notebooks.)

Wittgenstein, L.J.J. (1974) *Philosophical Grammar*, ed. R. Rhees, trans. A. Kenny, Oxford: Blackwell.(Written in 1931-4, this deals extensively with logic and mathematics, as well as topics such as language and meaning.)

Wittgenstein, L.J.J. (1975) *Philosophical Remarks*, ed. R. Rhees, trans. R. Hargreaves and R. White, Oxford: Blackwell.(Written in 1929-30 and interesting in that it shows the kinds of reflection on the *Tractatus* which drove Wittgenstein from his earlier to his later outlook.)

Wittgenstein, L.J.J. (1977a) *Remarks on Colour*, ed. G.E.M. Anscombe, trans. L.L. McAlister and M. Schättle, Oxford: Blackwell.(All the material on this topic from the writings of 1950-1, in which Wittgenstein worked on it extensively.)

Wittgenstein, L.J.J. (1977b) *Vermischte Bemerkungen*, Suhrkamp Verlag: Frankfurt am Main; trans. P. Winch, ed. G.H. von Wright and H. Nyman, *Culture and Value*, Oxford: Blackwell, 1980.(Wittgenstein's notebooks and typescripts often contain remarks on topics which are not directly philosophical. This collection assembles all of them from 1914 to 1951.)

Wittgenstein, L.J.J. (1980) *Remarks on the Philosophy of Psychology*, vols 1 and 2, ed. G.E.M. Anscombe and G.H. von Wright, trans. G.E.M. Anscombe, Oxford: Blackwell. (Selections made by Wittgenstein in 1947 and 1948 from material written in 1946-8. Contains much of interest on the topics treated in Part II of the *Philosophical Investigations*.)

Wittgenstein, L.J.J. (1982; 1992) *Last Writings on the Philosophy of Psychology*, ed. G.E.M. Anscombe, G.H. von Wright and H. Nyman, trans. C.G. Luckhardt and M.A.E. Wittgensteinian ethics

Although the strict 'fact-value distinction' of Wittgenstein's early period has shaped much subsequent work on ethics, his most profound influence on the subject stems from the later Philosophical Investigations and associated writings. Of particular significance have been, first, the concept of a 'language game', and second, the discussion of following a rule. The vision of morality itself as a language game - a complex of speech and action ordered in a way that makes sense to the participants - has seemed to diminish the urgency of traditional questions about the 'foundations' of ethics, and has promoted acceptance of moral experience and consciousness as natural (human) phenomena. More recently there has been a growing interest in how Wittgenstein's general reflections on rule-governed practices might apply to the specific case of moral understanding.

1 The early Wittgenstein

Wittgenstein once told a friend that, although he was not a religious man, he could not help seeing every problem from a religious point of view (Rhees (ed.) 1984: 79). Given the austerity of much of his philosophical subject matter, the statement is a curious one. However, it is a useful reminder that throughout his career he was in search not just of intellectual insight but of a correct attitude to life. This is already apparent in the first phase of his work.

The main ethical theme of Wittgenstein's *Tractatus Logico-Philosophicus* (1921), and the subject of his 'Lecture on Ethics' (1929), is the inexpressibility of (absolute) value. He bases this idea on a distinction between the world as a whole, or the 'totality of facts', and the particular facts that obtain within the world. Whereas the latter can be represented linguistically, anything we may say about the former will be 'nonsense' (even if it is the special kind of nonsense exemplified by all the propositions of the *Tractatus*). But since any given fact might have been otherwise, and is thus a mere accident, Wittgenstein holds that the entire domain of fact - and hence of what can be put into words at all - is, from an absolute standpoint, devoid of value. Ethics therefore - along with aesthetics - has to do not with particular facts but with the totality, or rather with the way in which the totality presents itself to us; and this in turn depends on the quality of our will - not the empirical 'will' recognized by psychology, but one whose good or bad exercise makes the world 'wax and wane as a whole'.

Wittgenstein mentions in the 'Lecture' some states of mind that seem to possess this transfigurative power: 'wondering at the existence of the world', 'feeling absolutely safe' and 'feeling guilty'. However, he stresses that one can speak only for oneself about such experiences and that language can in any case do no more than gesture towards what is important in them. We rely here on (apparent) allegory or simile of a kind that is essentially unconvertible into literal factual statement.

These views reflect Wittgenstein's desire to safeguard the private, spiritual nature of ethics and not to let it be demeaned by philosophical 'chatter'. Even at a more practical level, though, he sees little scope for discursive argument about moral questions. An individual may or may not 'have an ethics'; if so, then they will have a basis (be it Christian, Nietzschean, or whatever) for their life choices; but the question whether one *ought* to be a Christian or a Nietzschean is senseless, since there is no suitably authoritative standard by which to settle it.

2 Describing language games

One offshoot of this conception of value was the 'noncognitivist' theory of ethics, which classifies the functions of language under the two main headings of description and expression (see Analytic ethics). Wittgenstein himself, by contrast, moved during the 1930s towards an appreciation of the indefinite variety of 'language games' or types of rule-governed linguistic activity. In *Philosophische Untersuchungen (Philosophical Investigations)* (1953), our main source for his later thought, he sees language-use as part of our 'natural history' - one of those elements in human life that are given rather than chosen, and so 'have to be accepted'. This does not mean that 'good', in the ethically interesting sense, can after all be analysed ('naturalistically') in terms of a value-free notion of human welfare (see Naturalism in ethics). What it means is that the proper aim of moral philosophy (like that of philosophy in general) is not justification but a certain kind of clarity, and that its proper method is one of reflection on what we might do or say in various concretely imagined contexts - not of trying to formulate universal normative principles that would validate our behaviour.

This approach was seen by its exponents in the 1950s and 60s partly as a check on the pretensions of ‘theory’, but it also yielded illuminating discussions of familiar moral practices, which could now be accorded the same respect as the ‘alien’ anthropological phenomena conjured up in some of Wittgenstein’s thought experiments. A practice, it was argued, generates its own characteristic patterns of reasoning, and theorists are wrong to suppose that the behaviour internal to it admits of any better explanation than can be gathered from the participants themselves. Thus if someone (presumably a child) does not understand punishment, what we actually provide is help in seeing how the concept of punishment relates to others within the same region of social experience, such as wrongdoing, responsibility, forgiveness, making amends. And this is all the ‘explanation’ needed.

The view that philosophy should limit itself to ‘describing language games’ without passing judgment on them may seem to lead in the direction of relativism, a tendency already discernible at the end of §1 (see Moral relativism). It should be remembered, though, that Wittgenstein officially holds ‘ordinary’ (as opposed to philosophical) language to be in perfect order as it is, so that if our (ordinary) ethical language game happens to incorporate activities of critical observation and reflection, there would seem to be no (philosophical) reason why we should renounce these. Such activities might well go against Wittgenstein’s own anti-modern, even primitivist taste; but in keeping with the nonjudgmental attitude, he states no principle by reference to which they could be condemned. (Relatedly, one might ask about the ‘we’ that figures in this section: who exactly counts as being located outside ‘our’ moral practices, and so beyond the reach of ‘our’ judgment? (see Moral agents; Universalism in ethics §1).)

3 Rule-following and ethics

During the 1970s and 80s Wittgenstein studies took a new turn, the effect of which was felt in ethics. Partly in response to Saul Kripke’s reappraisal of the ‘rule-following considerations’, attention began to focus less on the specificity of particular language games and more on the idea of a rule-governed practice as such - the genus that includes all ‘games’ involving conventional signs (see Meaning and rule-following §3). Above all, how should we understand Wittgenstein’s account of the way a rule or order can ‘reach into the future’ and determine in advance what will and will not comply with it?

Because of the prominence it gives to the notion of criteria and to communal standards of correctness, Wittgenstein’s later philosophy has often been regarded as ‘anti-realist’. However, the rule-following considerations can be interpreted in a way that challenges this view and gives more weight to Wittgenstein’s own metaphysical ‘quietism’ - his disavowal of any substantive philosophical position. This different interpretation is unfavourable, in particular, to theories that refuse to take at face value the ostensibly factual character of certain regions of discourse. For example, it is opposed to the neo-Humean view that evaluative judgment cannot be genuinely factual because it involves a projection of our subjective attitudes onto the world (see Projectivism).

In the spirit of Wittgenstein’s remark that ‘words are also deeds’ (1953: part I, 546), and of the link he sets up in *Philosophische Untersuchungen* between linguistic understanding and socialization, the ‘quietist’ reading gives a central place to the ethical in reconstructing his overall account of rules. Wittgenstein notes that interpretation, explanation or justification necessarily ‘comes to an end’, giving way - if successful - to a moment when we see the point (or grasp the message) without the mediation of any further signs. The possibility of such immediate, tacit understanding is ultimately due to our common nature as members of an animal species, but the human species is distinguished from others by the fact that it exploits this natural ‘likemindedness’ in order to transmit to successive generations the various culturally distinct forms of likemindedness realized in particular languages. The work of socialization carried on within human cultures maintains in existence an array of shared sensibilities - the ‘feel’ speakers have for what a rule-governed practice requires in this or that particular case - and it is these sensibilities that support all our resources of normative judgment, whether about overtly ethical ‘right’ and ‘wrong’ or about right and wrong ways of describing things, right and wrong conclusions to draw from given premises, and so on.

Wodeham, Adam (*c*.1298-1358)

An English Franciscan theologian, Wodeham was preoccupied with logical and semantic questions. He lectured for about a decade on Peter Lombard's Sentences, *first at London, then at Norwich and finally at Oxford. His lectures emphasized the dependence of the created world on God and the contingency of nature and salvation.*

John Duns Scotus and William of Ockham exerted the most important influences on Wodeham. He regarded Scotus as a vigorous thinker and respected him enough to accept his opinion in case of doubt. Proud to have learned logic from Ockham, Wodeham devoted considerable time to defending Ockham's views from Walter Chatton, whom he saw as someone whose errors in logic arose from malice as well as ignorance. However, despite Wodeham's reservations about Chatton, he was considerably influenced by him. Similarly, Wodeham modified his own opinion about sensory illusions in response to Peter Aureol, whom he saw as skilled and prudent but often mistaken, sometimes as a result of faulty logic.

1 Psychology

Appealing to experience, Wodeham denied the distinction between the sensory and intellective souls; a single soul suffices to explain all the cognitive acts we perform. On this point, Wodeham opposed both Duns Scotus (who proposed formally distinct sensory and intellective souls) and Ockham (who proposed souls that were really distinct). Against Ockham's opinion that sensory and intellective souls must be distinct since contraries could not coexist in the same subject, Wodeham argued that sensory inclination and intellectual appetite in regard to the same external object were only virtually, not formally, contraries. The same soul apprehends sensible particulars and universals. These acts are sensations when they are partially caused by external objects; intellections, when they abstract from singulars (*Lectura secunda* I, 9-33).

A similar predilection for reductionism reveals itself in Wodeham's discussion of enjoyment. He claims that all appetitive acts are cognitive acts, since we cannot will or desire an object without apprehending it; but cognition does not necessitate volition. Like Ockham, Wodeham holds that clear knowledge of God without enjoyment is possible, at least at first. Conversely, loving God necessarily includes the implied judgment that God is lovable. This leads Wodeham to conclude that acts of volition can be described as true or false. Rejoicing about being a Franciscan, for example, includes the correct apprehension of a practical truth as well as the act of enjoyment (*Lectura secunda* I, 253-85).

2 Epistemology

Scepticism is a problem for Wodeham, who sees Ockham's response to it as inadequate. For Ockham, intuitive cognition, the basis of all other cognition, is reliable by definition. By contrast, Wodeham holds that whether or not the object of intuition exists, intuition will always incline us to believe that its object exists. He was among the first to recognize that sceptical consequences could be drawn from the long list of sensory illusions adduced by Peter Aureol against Scotus' account of intuitive cognition. In response, Wodeham defined three degrees of certainty. The greatest degree, which compels the intellect, is not available regarding contingent propositions, since the intellect is aware of the possibility of deception. The least degree of certainty is compatible with error. It is in this degree that I may be certain of a mistaken proposition - as for example, when I judge that a straight stick half submerged in water is bent.

Despite his preoccupation with possible natural and supernatural obstructions in the perceptual process and the concessions he made to them, Wodeham remained a reliabilist, maintaining that cognition is reliably though not infallibly caused by its object. His basic reply to the sensory illusions adduced by Aureol was that although illusions will continue to incline us to make false judgments, reason and experience enable us to correct our judgments and to avoid being systematically misled by illusions (*Lectura secunda* I, 65-111, 163-79) (see Epistemology, history of).

3 Semantics

In semantics, Wodeham's most important contribution was the concept of the *complexe significabile* (complexly signifiable) (see Language, medieval theories of). Wodeham developed his views as a compromise between

Chatton and Ockham on the question of the object of scientific knowledge. What is the object of our assent when we assert that man is a rational animal? Is it an external object in the real world (Chatton's *res*) or a mental object (Ockham's *complexum*)? Are we assenting to man considered as a rational animal, or to the complex mental entity that-man-is-a-rational-animal? Wodeham argues against both solutions. If Chatton is right, then there is no difference between a Catholic who asserts that Christ was incarnate and a heretic who asserts that Christ will be incarnate. Both assent to Christ as incarnate; the difference between their creeds can only be expressed by the tense of the verbs which connect Christ and incarnation. If Ockham is right, then sciences of real things deal only with mental objects and not with the external world; the objects of the 'real' sciences do not differ from the objects of logic and semantics. Such considerations lead Wodeham to postulate a third way: the true object of assent is what is complexly signifiable by a phrase, such as that-man is-a-rational-animal, the *complexe significabile* (Nuchelmans 1980).

The *complexe significabile* itself is neither something in the external world nor a mental object. It is neither a substance nor an accident and thus is not included in any Aristotelian category. It is not something, but neither is it nothing. Rather, the question 'What is it?' is ill-formed; it makes no more sense than the question 'Is a people a man or a non-man?' When we assent to a *complexe significabile*, we are not assenting to some thing; instead we are affirming that something is the case (*Lectura secunda* I, 180-208).

4 Logic

A terminist logician and a conceptualist, Wodeham employs three different kinds of supposition: personal, simple and material. Personal supposition is reference to things in the external world, simple supposition to concepts, and material supposition to written or spoken words (see Language, medieval theories of; Logic, medieval).

Wodeham's analysis of the distinction between abstract and concrete predication was indebted to but different from that of Ockham. In defining concrete predication, Wodeham aims to avoid generating nonsense expressions. Thus for Wodeham the nominal definition of the term *albus* is 'having whiteness', not 'body having whiteness'. Eliminating the bearer from the definition of concrete terms prevents the generation of the nonsense-sentence 'Socrates is a body having whiteness body', which would otherwise result from replacing 'white' with its definition in the sentence 'Socrates is a white body' (*Lectura secunda* II, 244).

Wodeham's denial that the bearer is signified *per se* in concrete predication is reminiscent of Anselm's distinction between *per se* and *per aliud* predication (see Anselm of Canterbury). For Wodeham as for Anselm, reference is signification only in a secondary sense. What we think of when we hear a term is not necessarily the objects to which it refers (its *supposita* or *appellata*). There is no difference between the *per se* signification of abstract and concrete terms; and in the case of substance terms, supposition and signification coincide. Thus both 'man' and 'humanity' signify and supposit for a substance composed of body and soul. The sentence 'A man is a humanity' is false only in the case of Jesus, who has a divine as well as a human nature and hence cannot be identified with his humanity (Spade 1988).

Wodeham relies on his theory of *per se* predication in dealing with problems of Trinitarian theology. The chief problem was the apparent conflict between the Aristotelian principle of non-contradiction and the truths of the faith. Thus Aristotelian logic seems to require that if 'the Father is not the Son' and 'the Father is the deity', then 'the deity is not the Son'. Confronting this problem, Wodeham rejects *ad hoc* theological modifications of logic; such approaches, he says, deserve the ridicule of heathens. Wodeham also criticizes the solutions of Ockham and Scotus. His own solution is to treat identity as a special case of predication; identity is not necessarily a symmetrical relationship (see Identity). Following Scotus, Wodeham distinguishes between identifying or formal predication and denominative predication. Unlike denominative predication, where the subject and predicate have the same supposition, in formal predication the predicate has broader supposition than the subject. Thus deity can be formally predicated of the Father, but the converse is not true (*Lectura Oxoniensis* I d.33; Gelber 1974).

5 Metaphysics

Wodeham was a conceptualist who identified universals with mental acts, and hence maintained that only individuals exist (*Lectura secunda* I, 21). In this respect, as in his emphasis on ontological parsimony, Wodeham followed Ockham (see Nominalism; Universals).

Considering proofs for God's existence, Wodeham analyses fourteenth-century Franciscan theories of causality. He defends Ockham's challenge to Scotus' inference: 'since the universe of essentially ordered effects is caused, the universe must be caused'. Exploiting his understanding of the logic of infinity, Wodeham argues that Chatton's defence of Scotus' theory of essentially ordered causes and effects is absurd. Chatton errs by inferring categorematic conclusions from premises which are true only if understood syncategorematically (*Lectura secunda* II, 117-21; Adams 1993).

6 Natural philosophy

In opposing the atomism or indivisibilism of his day, Wodeham repeatedly applied his understanding of the logic of infinity, continuity and infinitesimal change (see Natural philosophy, medieval). Like Ockham he believed that limits of place, time and motion - such as points, lines, surfaces, temporal instants and mutations (instants of change) - had no independent ontological status. Indeed, Wodeham says he anticipated Ockham's arguments for non-entitism, the claim that terms such as 'point' are non-referring (*Tractatus de indivisibilibus* q.2 a.1 n.20).

Wodeham presents many arguments against indivisibilism. Some depend on the distinction between the categorematic (perfectively actualized) and syncategorematic (processively actualized) meaning of the phrase 'infinitely divide'. Others, based on an analysis of the compounded and divided senses, claim that strictly speaking not the continuum, but its parts are divided. Most instructive in his view were arguments relying on the impossibility of indivisibles in contact with one another.

Wodeham accepted Ockham's claim that the infinity of parts in a continuum exists not just potentially but actually. Acceptance of this claim led Wodeham to argue for the possibility of unequal infinities (*Tractatus de indivisibilibus* q.5).

7 Influence

Although Ockham died in 1347, less than forty years after Scotus, Wodeham saw Scotus as an 'ancient' author and Ockham as a modern contemporary. Respectful but seldom vitally concerned with his views, Wodeham calls Thomas Aquinas the *Doctor communis* (Universal Doctor). Many subsequent authors, even in the fifteenth century, saw the history of philosophical theology in the same way (Courtenay 1978). Wodeham's view of the history of thought was based less on the dating of authors than on the extent to which their theology was characterized by explicit appeals to logical arguments. The continued currency of his views is a measure of his influence.

Huge crowds flocked to Wodeham's lectures in the 1330s, and John Major held that Wodeham would be reputed a greater philosopher than Ockham were it not for Ockham's political writings. However, almost nothing by or about Wodeham was published in the four centuries between 1512 and 1976. Despite a spate of recent publications on Wodeham, comparatively little is or can be known about his views until a critical edition of his most important work is prepared.

REGA WOOD

List of works

Wodeham's most significant works were three sets of theology lectures based on Peter Lombard's *Sentences*. His first lectures, delivered in London, have not been independently preserved, though portions are included in his second lectures. His second lectures (*Lectura secunda*), intended for a Franciscan audience in Norwich, were first published in 1990. The final lectures, written for a larger Oxford audience, are his most influential work but still await publication. In the Renaissance, John Major chose to print Henry Totting von Oyta's abbreviation of the Oxford lectures, rather than the work itself. Lost works by Wodeham include two Bible commentaries (on the *Canticum Canticorum* and on *Ecclesiasticus*), a set of *Determinationes* and a treatise against Richard of Wetherset, defending the right of friars to hear confessions.

Wodeham, Adam (after 1323, before 1331) *Tractatus de indivisibilibus*, ed. R. Wood, Dordrecht: Kluwer, 1988. (Wodeham's longest sustained discussion of issues in natural philosophy, which quotes frequently from Ockham's *Physics*. Also printed here is Wodeham's *Quaestione de divsione et compositione continua*, dated 1322-31.)

Wodeham, Adam (before 1333) *Lectura Oxoniensis*, ed. J. Major, *Abbreviatio Henrici Totting de Oyta, seu Adam goddam super quattuor libros sententiarum*, Paris: P. le Preux, 1512.(This Renaissance edition prints Henry Totting von Oyta's abbreviation of the Oxford lectures, not the work itself. In addition to the bulk of *Lectura Oxoniensis*, this volume also includes Major's life of Wodeham.)

Wodeham, Adam (before 1339) *Lectura secunda*, ed. R. Wood and G. Gál, St Bonaventure, NY: St Bonaventure University, 1990.(Though limited to the first book of the *Sentences*, these three volumes include more than 1260 pages of exposition. The introduction discusses Wodeham's life and influence and summarizes some of his views. There is a bibliography in Vol. III.)

Wolff, Christian (1679-1754)

Christian Wolff was a rationalistic school philosopher in the German Enlightenment. During the period between the death of Leibniz (1714) and the publication of Kant's critical writings (1780s), Wolff was perhaps the most influential philosopher in Germany.

There are many reasons for this, including Wolff's voluminous writings in both German and Latin in nearly every field of philosophy known to his time, their unvarying employment of a strict rationalistic method to establish their conclusions, the attention directed to Wolff and his views as a result of bitter controversies with some theological colleagues, his banishment from Prussia by King Frederick Wilhelm I in 1723 and triumphant return from Hesse-Cassel in 1740 after Frederick the Great assumed the throne, and his active teaching at the Universities of Halle and Marburg for nearly 50 years. Through his work as a university professor, his prolific writings, and the rigour and comprehensiveness of his philosophy, Wolff influenced a very large group of followers, educators and other writers. Even after his influence had begun to wane, Kant still referred to 'the celebrated Wolff' and spoke of 'the strict method of the celebrated Wolff, the greatest of all dogmatic philosophers'.

Wolff thought of philosophy as that discipline which provides reasons to explain why things exist or occur and why they are even possible. Thus, he included within philosophy a much broader range of subjects than might now be recognized as 'philosophical'. Indeed, for Wolff all human knowledge consists of only three disciplines: history, mathematics and philosophy.

The reasons provided by Wolff's philosophy were to be established through unfailing adherence to a strict demonstrative method. Like Descartes, Wolff first discovered this method in mathematics, but he concluded that both mathematical and philosophical methods had their ultimate origins in a 'natural logic' prescribed to the human mind by God. In fact, the heart of Wolff's philosophical method is a deductive logic making use of syllogistic arguments.

For Wolff, the immediate objective of philosophical method is to achieve certitude by establishing an order of truths within each discipline and a system within human knowledge as a whole. The ultimate goal is to establish a reliable foundation for the conduct of human affairs and the enlargement of knowledge.

Wolff applied his philosophical method unfailingly in each of the three principal parts of philosophy: metaphysics - knowledge of those things which are possible through being in general, the world in general, human souls, and God; physics - knowledge of those things which are possible through bodies; and practical philosophy - knowledge of those things which are concerned with human actions. Wolff's philosophical system also includes logic, an art of discovery (to guide the investigation of hidden truth and the production of new insights), some experiential disciplines (for example, empirical psychology) and several bodies of philosophical knowledge that were not well developed in Wolff's time concerning law, medicine, and both the practical and liberal arts.

1 Life and works

Christian Wolff was born in Breslau, where he received his early education. He studied at the University of Jena and received a master's degree in 1703 at the University of Leipzig. In these settings, Wolff became familiar with Lutheran, Calvinist and Roman Catholic viewpoints in theology; Aristotelian, Scholastic and Cartesian school traditions in philosophy; and the emerging empirical methods of Newtonian science. The most important single influence on Wolff's thought was Leibniz. But Wolff resisted characterizations of himself as merely a follower or systematizer of Leibniz's thought. This unflattering stereotype first arose during Wolff's lifetime and is commonly heard today.

Leibniz provided a letter of recommendation which helped Wolff obtain his first teaching position as Professor of Mathematics and the Natural Sciences at the new University of Halle in 1706 where he taught and wrote about the subjects indicated, only gradually taking an interest in selected philosophical topics.

In 1713, Wolff published his *Vernünftige Gedanken von den Kräften des menschlichen Verstandes (Rational Thoughts on the Powers of the Human Understanding; referred to as the German Logic)*, an introductory handbook on logic. This became the most popular of all of Wolff's writings, appearing in fourteen different

editions during his lifetime. It was his only major philosophical work published during Leibniz's lifetime.

During the early 1720s, Wolff published a series of philosophical works in German. These included books on metaphysics (1720), ethics (1720), politics (1721), physics (1723), teleology (1724), and physiology (1725), many of which later appeared in numerous reprintings or new editions.

The titles of all of Wolff's central philosophical writings in German begin with the common phrase, 'Rational Thoughts on… '. For example, the *German Metaphysics* (published in twelve editions during Wolff's lifetime) bears the ambitious title, 'Rational Thoughts on God, the World, and the Human Soul, and All Things in General', indicating both the methodic rigour which the author prized and the ambitious scope of the work.

Together with a volume of annotations on the metaphysics (1724) and another (1726) offering a review and defence of all of Wolff's previous writings on the various parts of philosophy ('Weltweisheit'), these German publications contributed significantly to the establishment of the German language as a vehicle for scientific communication (Blackall 1959). In addition, during Wolff's lifetime Latin remained in wide use by scholars and other vernacular languages (for example, French) were far more advanced in their development than German.

Unfortunately, Wolff's writings and lectures entangled him in bitter quarrels with critics led by Pietist members of the theology faculty at Halle, such as Joachim Lange, and Johann Franz Budde at Jena (see Pietism). The issues had to do with the proper roles of reason and faith in human life, along with charges that Wolff's views implied a fatalistic and necessitarian view of the world, human beings and God. For example, it seemed heretical to Wolff's opponents for him to have said in a public lecture in 1721 that the pagan Chinese could develop a satisfactory ethical philosophy on the basis of reason alone without the assistance of the Christian revelation. Similarly, Wolff's acceptance of the Leibnizian doctrine of pre-established harmony and his emphasis on God's intellect as the controlling framework for divine freedom and power seemed to his critics to lead directly to a deterministic universe.

When Wolff did not give in to his critics and could not otherwise be bested, his opponents appealed to external authority. Without holding a hearing on the charges against him, King Frederick William I issued an order on 8 November 1723 that removed Wolff from his professorship and banned him from Prussia within forty-eight hours on pain of death.

Wolff was able to take up a teaching post previously offered to him at the University of Marburg in Hesse-Cassel. Official censure and exile only heightened his popularity. Nevertheless, Wolff decided to write no more in German and to turn to the wider intellectual world by composing a new series of philosophical publications in Latin, the dominant scientific language of the time. That series occupied the rest of his life.

Wolff's Latin works expanded and restated in a more thoroughgoing and systematic way his views on philosophy and other subjects. They began with a Preliminary Discourse on Philosophy in General (1728). Most of Wolff's Latin writings share a common subtitle, *methodo scientifica pertractata* ('treated according to the scientific method'). Thus, the Latin ontology volume is entitled, *Philosophia prima, sive Ontologia, methodo scientifica pertractata, qua omnis cognitionis humanae principia continentur (First Philosophy, or Ontology, Treated According to the Scientific Method, in Which Are Contained All of the Principles of Human Knowledge; referred to henceforth as the Latin Ontology).*

Wolff's Latin works include treatises on logic (1728), ontology (1729), general cosmology (1731), empirical (1732) and rational (1734) psychology, natural theology (2 vols, 1736-7), practical philosophy (2 vols, 1738-9), natural law (8 vols, 1740-8), international law (1749), ethics (5 vols, 1750-3) and economics (2 vols, 1754-5). In 1740, Wolff was recalled to the University of Halle where he became Chancellor in 1743. After a period of fame and influence, he died on 9 April 1754, the author of some seventy volumes of published work in mathematics and philosophy.

Wolff's distinctive contributions involve his description of the scope of human knowledge (comprising history, philosophy and mathematics), his definition of philosophy and its goals, his systematic description of the parts of philosophy, his views on philosophical method and some of his central metaphysical doctrines.

2 Human knowledge: history, mathematics and philosophy

Wolff divided all human knowledge into three basic types: (1) history or ’knowledge of those things which are and occur either in the material world or in immaterial substances’; (2) philosophy or ’knowledge of the reason of things which are or occur’; and (3) mathematics or ’knowledge of the quantity of things’ (*Preliminary Discourse* §§3, 6 and 14). This division is intended to organize human knowledge by finding the proper place for each division and identifying its role in the schema of human understanding.

According to Wolff, philosophy originates in experience or historical knowledge. Some historical facts are common to all, requiring only human attention and some acumen. Other facts ’do not spontaneously present themselves to one who is attentive’ (*Preliminary Discourse* §20). Such facts are hidden and must be sought out by observation, investigation, and experiments. Mathematics assists the search for such facts, as well as their philosophical explanation, by perfecting the evidence, guiding reason and confirming demonstrations.

3 Philosophy: definition and goals

Wolff defined philosophy more precisely as ’the science of the possibles in so far as they can be’ (*Preliminary Discourse* §29; École 1978). A key element here is the meaning of the term ’science’. ‘By science here I mean the habit of demonstrating propositions, that is, the habit of inferring conclusions by legitimate sequence from certain and immutable principles’ (*Preliminary Discourse* §30). Scientific knowledge is characterized by its method and order, that is, certain and immutable principles, methodic inferences, and orderly conclusions.

Wolff’s proximate goal in philosophy and the trait which is most typical of his writings was demonstration, the ’showing forth’ of conclusions distinguished by their certitude. Thus, he wrote that ‘nothing is more important than certitude’ (*Preliminary Discourse* §28). In fact, however, Wolff pursued certitude as the foundation upon which philosophy can best serve human interests and needs. Thus, he observed that ‘the fruit of philosophy… [is] its usefulness in knowledge and in life’ (*Preliminary Discourse* §116; compare Corr 1970).

4 The parts of philosophy

Wolff’s mature description of the parts of philosophy appears in Table 1 (compare Blackwell 1961b). The basic division is between those parts of philosophy that deal with things and those concerned with human actions. Within that, philosophical discussions of things are divided into metaphysics and physics, while practical philosophy is divided into ethics, economics and politics, together with some mention of philosophy of the arts and with an important role for logic or the philosophy of human cognition.

Table 1. Wolff's division of philosophy

Of things	**Of human actions**			
Metaphysics (being in general) (spirits) (the world in general)		Ontology (being in general)	Cognitive philosophy	Logic (directing the cognitive faculty in knowing truth and avoiding error
		General cosmology (the world in general)		Ars inveniendi (art of investigating or discovering hidden truth)
	Pneumatics (spirits)	Psychology (human souls)	Practical philosophy (directing the appetitive faculty in choosing good and avoiding evil)	Jus naturae or Law of nature (knowledge of good and evil actions)
		Natural theology		Universal practical

		(God)		philosophy (general theory and practice of practical philosophy
Physics (bodies)	General physics (general affections of all bodies or of many diverse species)			Ethics (directing man's free actions in the natural state or individual morality)
	Cosmology (world as such)			Economics (directing free actions in smaller societies distinct from the state)
	Meteorology (atmospheric phenomena)			Politics (directing free actions in a civil society or state)
	Oryctology (minerals)		Philosophical knowledge of the arts	(reasons explaining the arts and works of art, whether medicine or law, practical arts such as wood cutting, agriculture, or civil architecture [technology], or the liberal arts (grammar, rhetoric, poetry)
	Hydrology (fluids)			
	Phytology (plants or vegetables)			
	Physiology (animated bodies)			
	Teleology (final cause of natural things)			

According to Wolff, ‘the beings which we know by examining ourselves before we philosophize are God, human souls and bodies’ (*Preliminary Discourse* §55). Natural theology is ’the science of those things which are known to be possible through God’; psychology is ’the science of those things which are possible through human souls’

(*Preliminary Discourse* §§57-8). In addition, ontology or first philosophy is ’the science of being in general, or in so far as it is being’, and general cosmology is ’the science of the world in general’ or of that which is common to the existing world and to any other possible world (*Preliminary Discourse* §§73 and 78).

Together, natural theology and psychology make up ’pneumatics’ or ’the science of spirits’; along with ontology and general cosmology, these four bodies of philosophical knowledge constitute ’metaphysics’ (*Preliminary Discourse* §79).

Physics is ’the science of those things which are possible through bodies’ (*Preliminary Discourse* §59). It includes general physics (the science of those things which are common to all bodies or to many diverse kinds of bodies), together with specific physical sciences of particular kinds of bodies.

Practical philosophy is ’the science of directing the appetitive faculty in choosing good and avoiding evil’ (*Preliminary Discourse* §62). Its components address free human actions in different situations: ethics examines free actions in the natural state or when humans act as individuals; economics studies free actions within smaller societies distinct from the state; and politics explores free actions in a civil society or state. Practical philosophy also includes a general science or basic theory about good and evil actions (the law of nature or *jus naturae*), and a body of knowledge about the general theory and practice of practical philosophy (universal practical philosophy). Wolff acknowledged that these last two sciences (presumably, along with *jus gentium* or international law which he developed later) could in principle be treated as subordinate parts of ethics, economics, and politics, but he preferred to keep them separate for the sake of clarity and demonstrative rigour.

Within his discussion of human action, Wolff admitted the possibility of philosophical knowledge about the arts, whether these are the practical arts like wood cutting, agriculture, or civil architecture, bodies of knowledge like law and medicine, or the liberal arts like grammar, rhetoric and poetry. Nevertheless, he acknowledged that philosophers had not previously given much attention to the reasons behind these types of human arts.

Logic is ’the science of directing the cognitive faculty in the knowing of truth’ and avoiding error (*Preliminary Discourse* §61). Because logic guides all of philosophy, Wolff recommended that it be given first place among philosophical disciplines. However, to demonstrate its own rules, logic must follow ontology and psychology from which its principles are derived. In addition to logic, Wolff also commended a new body of knowledge called the ’art of discovery’ (*ars inveniendi*) (*Preliminary Discourse* §74) intended to guide the investigation of hidden truth by following the example of algebra and the analytic arts of the mathematicians (Corr 1972).

Wolff believed ‘there are many philosophical disciplines which still lie hidden’ (*Preliminary Discourse* §86). His review of the parts of philosophy was intended to organize those bodies of philosophical knowledge known to his time and to show that the various parts of philosophy must be ’ordered in such a way that those parts should come first which provide principles for the other parts’ (*Preliminary Discourse* §87; see Table 1).

Wolff chose the method of learning over the method of demonstration by beginning with logic because of its importance in leading to a knowledge of all other parts of philosophy. Also, Wolff believed that logic could easily explain the ontological and psychological principles which it needed.

Similarly, because ‘the principles of philosophy must be derived from experience’ (*Preliminary Discourse* §34), Wolff acknowledged the importance of observations and experiments in philosophy. In addition, he hoped to develop an art of discovery, and he distinguished between empirical and rational psychology (*Preliminary Discourse* §§111-12; see Blackwell 1961a; Corr 1975b). All of this was intended to contribute to ‘a marriage of reason and experience’ (*Latin Logic* §1232) within philosophy in particular and human knowledge in general.

Nevertheless, it is the requirements of demonstration that govern Wolff’s analysis of the parts of philosophy. Accordingly, metaphysics must precede physics and practical philosophy, and within each of these three primary philosophical disciplines the order of their subordinate parts should be that given in Table 1. Furthermore, demonstrative method is the most notable feature in each part of Wolff’s philosophy.

5 Philosophical method

‘Philosophical method is the order which the philosopher ought to use in treating dogmas’ (*Preliminary Discourse* §115). Furthermore, ‘the supreme law of philosophical method is that those things must come first through which

later things are understood and established' (*Preliminary Discourse* §133). In other words, method involves a certain kind of ordering of dogmas or propositions. It proceeds from accurate definitions and precise terminology to establish certain and immutable principles, legitimate deductions, and demonstrated conclusions. Initial conclusions become the bases for further inferences and deductions, all of which yields certitude and utility.

Like some contemporaries, Wolff believed that philosophical and mathematical method are fundamentally identical because they derive from a common source, the notion of certitude. Thus, he observed that 'philosophy does not borrow its method from mathematics; rather, both philosophy and mathematics derive their methods from true logic' (*Preliminary Discourse* §139). In his *Eigene Lebensbeschreibung (Autobiography)* (pp. 121-2, 143), Wolff wrote that he had studied mathematics in order to discover the key to its success and to apply this discovery to the improvement of philosophy, theology, and the art of discovery. This reflects Wolff's commitment to a 'natural logic' or set of 'rules prescribed by God to the understanding and the natural ability to act accordingly' (*German Logic*, ch. 16 §3; compare *Latin Logic* §6; also Corr 1970).

Unlike others, Wolff found in the categorical syllogism what he understood to be the basic principles and the best expression of true logic and philosophical method. 'By these syllogisms everything is found out that can be discovered by human understanding, and everything is proven to others that they want to be convinced of, although neither in discovering nor in demonstrating do we always have the form of the syllogisms distinctly before our eyes' (*German Logic*, ch. 4 §20; compare *Latin Logic* §50). Thus, 'a syllogism is a speech in which reasoning or discourse is distinctly stated' (*Latin Logic* §332).

Whenever certitude cannot be established, a principle of tried usefulness can be admitted into philosophy as a probability or hypothesis, that is, 'an assumption which cannot yet be demonstrated, but which provides a reason' (*Preliminary Discourse* §126). This recognizes that, 'probability, in so far as it is clearly distinguished from certitude, is not to be eliminated from philosophy' (*Preliminary Discourse* §132).

6 Selected metaphysical doctrines

As noted above, Wolff defined philosophy as 'the science of the possibles in so far as they can be' (*Preliminary Discourse* §29). Accordingly, natural theology is the science of that which is possible through God, physics the science of that which is possible through bodies, and so forth.

This means that philosophy must provide scientific or demonstrative explanations as to why anything is or is not intrinsically possible (that is, not inherently self-contradictory). Further, philosophy must also explain why any possible being actually does or does not exist. Wolff defined existence as the 'fulfilment of possibility' (*German Metaphysics* §14) or the 'complement of possibility' (*Latin Ontology* §174; Van Peursen 1987).

Within Wolff's system, 'ontology or first philosophy is defined as the science of being in general, or in so far as it is being' (*Latin Ontology* §1; École 1990). Ontology is rooted in two central axioms which apply equally to the orders of being and of knowing (there is no separate, explicit discussion of theory of knowledge within Wolff's philosophy; see Gracia 1994). These fundamental axioms are the principle of contradiction and the principle of sufficient reason. The first and most basic is the principle of contradiction: 'it cannot happen that the same thing is and is not' (*Latin Ontology* §28). The principle of sufficient reason ('nothing exists without a sufficient why it is able to be rather than is not'), is explicitly subordinated to and deduced from the principle of contradiction (*Latin Ontology* §70). Following these two fundamental principles, every philosophical explanation must demonstrate two things about the subject matter in question: (1) that it is not impossible, that is, not inherently self-contradictory; and (2) that there is a sufficient reason why it actually exists or occurs.

'Being' is defined by Wolff as 'that which is able to exist, that is, to which existence is not repugnant' (*Latin Ontology* §134). The structure of being depends on three principal components: (1) 'essentialia' or ultimate factors within a being characterized by their lack of mutual determination and contradiction; (2) 'attributes' or constant factors which depend on 'essentialia' to explain their possibility and actuality; and (3) 'modes' or variable elements which must be compatible with its 'essentialia', but whose actual presence depends on external factors such as circumstances and other agents (*Latin Ontology* §§143, 146 and 148).

Both Wolff's ontology and general cosmology are notable for not including the Leibnizian doctrine of monads (see Leibniz, G.W. §§4-5). Wolff described the world and the bodies within it as complex or compound entities

constituted by the interconnection of simpler entities (*General Cosmology* §§48 and 119). Ultimately, the most fundamental of these simple substances or 'elements' are indivisible, physical points or 'atoms of nature' (*General Cosmology* §187) which are imperceptible and simple. They lack extension or figure, but are not characterized by a spiritual force or the perceptual activity of Leibniz's monads.

As noted above, Wolff divided psychology into 'empirical' and 'rational' parts (Blackwell 1961a; Corr 1975b). This division respects the need to incorporate observation and experience within philosophy, although the way in which the two parts of psychology are implemented reflects Wolff's search for demonstrative conclusions. Thus, empirical psychology organizes the facts of our psychological experience through an extended review of human cognitive and appetitive operations, and an attempt to define the basic vocabulary of psychology. It also offers a pivotal argument for the existence of the human soul:

> Whatever being is actually conscious of itself and of other things outside itself, that being exists. But we are actually conscious of ourselves and of other things outside ourselves. Therefore we exist.
>
> (*Empirical Psychology* §16)

On this basis, rational psychology provides a definition of the essence of the human soul: 'The essence of the soul consists in the force of representing the universe limited materially by the placement of the organic body in the universe and formally by the constitution of the sensory organs' (*Rational Psychology* §66).

Wolff's psychology accepted a classic dualism between soul and body (*Rational Psychology* §§530-642). Ideally, empirical psychology would disclose the simultaneous occurrence of mental and bodily actions, while rational psychology would systematically explain their interdependence. However, Wolff conceded that he had not been able to find any reason in the nature of the soul from which the necessity of its 'commerce' or interaction with the body could be deductively demonstrated. As a result, he resorted to a hypothetical explanation. Among possible candidates for this, both direct physical influx or interaction and occasionalism were rejected as unlikely (see Occasionalism), while Leibniz's theory of pre-established harmony (see Leibniz, G.W. §6) was accepted as the most likely account (*Rational Psychology* §639). However, in Wolff's view pre-established harmony was not without its own difficulties and was admitted only as a probable explanation limited to the relationship between the human soul and body.

Natural theology is 'the science of those things which are possible through God' (*Natural Theology* I §1). By contrast with a supernatural or revealed theology originating in a divine revelation or sacred scripture, natural theology proceeds 'solely by the light of nature' (*Natural Theology* I §1n). Nevertheless, for Wolff 'there is no more sublime philosophy than that which clearly demonstrates the highest perfections of the supreme divinity and how all things are in it, from it, and through it, and which completely roots out the profane thoughts of men concerning God and religion' (*Natural Theology*, dedication to Part I).

Wolff divided natural theology into two major parts: Part I contains an a posteriori demonstration of the existence and attributes of God drawn from the characteristics of the visible world; Part II treats the same subjects from an a priori standpoint based on the notion of a most perfect being and the nature of the human soul (Bissinger 1970; Corr 1973). The a posteriori argument for the existence of God is complex (compare, *Natural Theology* I §§24 onwards): the human soul exists or we exist; there must be a sufficient reason why this is so; that reason must be contained either in ourselves or in some other being different from us; in either case, the reason must lie in a necessary being if it is to be truly sufficient; therefore, a necessary being exists; a necessary being is an *ens a se* (being in itself) or one which contains the sufficient reason of its existence in its own essence, that is, an '*ens a se* exists therefore, because it is possible' (*Natural Theology* I §34); neither the visible world, its elements, or the human soul can be *ens a se*; therefore, God exists; 'God' being defined nominally as 'the *ens a se* in which is contained the sufficient reason of the existence of this visible world and of our souls' (*Natural Theology* I §67).

Wolff noted that an *ens a se* (in contrast to an *ens ab alio* or being from another) is possible because its essential constituents involve no contradiction; it exists because it possesses these particular essential determinations. The fact that its essential constituents explain both its possibility and its actual existence is the special 'privilege' of an *ens a se*. 'And thus it is that existence is not inferred from possibility in general, nor is existence determined from possibility considered in general or in itself' (*Natural Theology* I §34n).

Wolff's a priori proof for the existence of God was based on the notion of an *ens perfectissimum* or 'most perfect

being' understood as that being 'to which belong all compossible realities in the absolutely highest degree' (*Natural Theology* II §6). The *ens perfectissimum*, nominally defined as God, contains in the highest degree all of the real or ontological components of the essence of a being which are both possible in themselves and in relation to each other. On this basis, the a priori demonstration of God's existence is this:

> God contains all compossible realities in the absolutely highest degree. But He is possible. Wherefore, since the possible can exist, existence can belong to it. Consequently, since existence is a reality, and since realities are compossible which can belong to a being, existence is in the class of compossible realities. Moreover, necessary existence is the absolutely highest degree. Therefore, necessary existence belongs to God or, what is the same, God necessarily exists.
>
> (*Natural Theology* II §21)

In other words, 'God exists through His essence or His existence is essential' (*Natural Theology* II §27).

The principal attributes of God are intellect, power, and will. The divine intellect explains the intrinsic possibility of the world (its lack of internal self-contradiction), the divine power explains its extrinsic possibility (or compatibility with the nexus of other existents that together constitute a particular universe), and the divine will accounts for its actual existence (by providing the sufficient reason for or final determination of that existence). In addition, 'God wills whatever He represents to Himself as the best, both in itself and in relation to Himself' (*Natural Theology* I §390). Thus, the visible universe is the best of all possible worlds. But Wolff believed God may bring other possible worlds - one or all of them - into actual existence along with the best one. Therefore, Wolff maintained that the existence of any world is only a contingent fact. God acts reasonably, but the divine creative act is not coerced or necessitated by the objective, existential dynamism of a world of possible essences.

7 Practical philosophy

Wolff wrote extensively on various areas of practical philosophy, but that portion of his philosophy has had less influence than his views on method and metaphysics. Contrary to radical fideists, Wolff argued for a moral philosophy based on the concept of perfection (*German Ethics* §2). The good is that which makes us and our condition more perfect; the bad is that which makes us and our condition more imperfect. These notions arise from the structure of being and can be known by human beings through natural reason even without the assistance of Christian revelation. In short, neither the good nor our knowledge of the good are directly dependent upon God's will or influence.

Perfection involves self improvement, both in internal and external conditions, as well as the improvement of other human beings and the promotion of God's honour. In striving for this extended concept of perfection, human beings are acting according to a natural moral law, one which applies to individuals, small communities, nation states, and the international human community. The idea of perfection is the fundamental motivating force in the practical sphere. Thus, intellect or reason directs the will in the search for an objective moral good. And education or the formation of clear and distinct ideas associated with perfection is the chief spur to moral living. Here is the ultimate outcome of Wolff's conviction that clear and certain ideas are the best foundation for both the advancement of theoretical knowledge and practical living.

8 An assessment

Christian Wolff is not a first-rank, original thinker. He was important in particular as an organizer and systematizer of philosophical thought during the eighteenth century. Wolff's thought emphasized clarity, rigour and comprehensiveness. In the history of German philosophy, Wolff was the first major systematic thinker. His philosophical system helped to define important philosophical terms and advance the cause of the German language as a tool for scholarly work.

Leibniz was the single most important influence on Wolff's thought. But Wolff did not like to be regarded merely as someone who gave a new and more orderly presentation to the views of his great predecessor (*Autobiography*: 142-3). In fact, there were important limitations in what the two men knew of each other's writings and Wolff departed from Leibniz's views on several key points (Corr 1975a). In addition, Wolff drew upon other sources as well (Corr 1983). And Wolff helped to make room for the emerging sciences of his day, even though his own deductive methodology in philosophy was not wholly compatible with the methods of those sciences.

Through his lengthy teaching career, extensive writings, and many followers, Wolff was extremely influential in shaping German philosophical thought for a period of fifty years and more during the middle of the eighteenth century. Against the Pietists who became his opponents, Wolff spoke on behalf of what he regarded as the legitimate claims of natural human reason, as well as the compatibility of faith and reason (École 1983). In defending his own views, he composed extended refutations of atheism, deism, fatalism, naturalism and Spinozism (Morrison 1993). In reaction to censure from his theological critics and political opponents, Wolff also wrote eloquently on behalf of the freedom to philosophize (*Preliminary Discourse* §§151-71), arguing that 'if one is to use philosophical method in developing philosophy, then the yoke of philosophical servitude cannot be imposed' (§153). Praised by Kant for the rigour of his thought, Wolff helped to frame many of the issues addressed by his great successor.

List of works

Wolff, C. (1964-) *Christian Wolff's Gesammelte Werke (Collected Works)*, Hildesheim and New York: Georg Olms.(Wolff's collected works are being reprinted in three series: German writings; Latin writings; and a supplementary series of materials and documents relevant to Wolff's life, works and thought. This very large publishing project is now almost complete. It consists of a total of 109 separate volumes: 29 German, 41 Latin and 39 supplementary.)

1 German series

The principal works of philosophical importance in the German series are given here.

Wolff, C. (1713) *Vernünfftige Gedancken von den Kräfften des menschlichen Verstandes und ihrem richtigen Gebrauche in Erkänntnis der Wahrheit*, trans. as *Logic, or Rational Thoughts on the Powers of the Human Understanding, with Their Use and Application in the Knowledge and Search of Truth*, London: L. Hawes, W. Clarke & R. Collins, 1770.(Referred to as the *German Logic*; translated anonymously into English.)

Wolff, C. (1720) *Vernünfftige Gedancken von Gott, der Welt und der Seele des Menschen, auch allen Dingen überhaupt (Rational Thoughts on God, the World and the Human Soul, and All Things in General)*.(Referred to as the *German Metaphysics*.)

Wolff, C. (1720) *Vernünfftige Gedancken von der Menschen Thun und Lassen, zu Beförderung ihrer Glückseeligkeit, den Liebhabern der Wahrheit mitgetheilet (Rational Thoughts on Human Conduct)*.(Referred to as the *German Ethics*.)

Wolff, C. (1721) *Vernünfftige Gedancken von dem gesellschaftlichen Leben der Menschen und insonderheit dem gemeinen Wesen zu Beförderung der Glückseeligkeit des menschlichen Geschlechts (Rational Thoughts on the Social Life of Humans and Especially the Commonwealth for the Promotion of the Happiness of the Human Race)*.(Referred to as the *German Politics*.)

Wolff, C. (1723) *Vernünfftige Gedancken von den Wirkungen der Natur, den Liebhabern der Wahrheit mitgetheilet (Rational Thoughts on the Operations of Nature*.(Referred to as the *German Physics*.)

Wolff, C. (1724) *Vernünfftige Gedancken von den Absichten der natürlichen Dinge, den Liebhabern der Wahrheit mitgetheilet (Rational Thoughts on the Purposes of Natural Things)*.(Referred to as the *German Teleology*.)

Wolff, C. (1724) *Anmerckungen über die vernünfftige Gedancken von Gott, der Welt und der Seele des Menschen, auch allen Dingen überhaupt, zu besserem Verstande und bequemeren Gebrauche derselben (Annotations to the Rational Thoughts on God, the World and the Human Soul)*.

Wolff, C. (1725) *Vernünfftige Gedancken von dem Gebrauche der Theile in Menschen, Thieren und Pflantzen, den Liebhabern der Wahrheit mitgetheilet (Rational Thoughts on the Use of Parts in Humans, Animals and Plants)*.(Referred to as the *German Physiology*.)

Wolff, C. (1726) *Ausführliche Nachricht von seinen eigenen Schrifften die er in deutscher Sprache von den verschiedenen Theilen der Welt-Weiszheit herausgegeben, auf Verlangen ans Licht gestellet (Detailed Account of His Own Works Which He Published in the German Language on the Different Parts of Philosophy)*.

Wolff, C. (*c*.1740) *Christian Wolff's eigene Lebensbeschreibung (Autobiography)*.

2 Latin series

The principal works of philosophical importance in the Latin series.

Wolff, C. (1718) *Ratio praelectionum Wolffianarum in mathesin et philosophiam universam (Plan of the Wolffian Lectures in Mathematics and Universal Philosophy)*.

Wolff, C. (1728) *Discursus praeliminaris de philosophia in genere*, trans. R.J. Blackwell, *Preliminary Discourse on Philosophy in General*, Indianapolis, IN: Bobbs-Merrill, 1963.(Originally published together with the *Philosophia rationalis sive Logica*.)

Wolff, C. (1728) *Philosophia rationalis sive Logica, methodo scientifica pertractata et ad usum scientiarum atque vitae aptata (Rational Philosophy or Logic, Treated According to the Scientific Method)*.(Referred to as the *Latin Logic*.)

Wolff, C. (1729) *Philosophia prima, sive Ontologia, methodo scientifica pertractata, qua omnis cognitionis humanae principia continentur (First Philosophy, or Ontology, Treated According to the Scientific Method)*.(Referred to as the *Latin Ontology*.)

Wolff, C. (1731) *Cosmologia generalis, methodo scientifica pertractata, qua ad solidam, inprimis Dei atque naturae, cognitionem via sternitur (General Cosmology, Treated According to the Scientific Method)*.(Referred to as the *General Cosmology*.)

Wolff, C. (1732) *Psychologia empirica, methodo scientifica pertractata, qua ea, quae de anima humana indubia experientiae fide constant, continentur et ad solidam universae philosophiae practicae ac theologiae naturalis tractationem via sternitur (Empirical Psychology, Treated According to the Scientific Method)*.(Referred to as the *Empirical Psychology*.)

Wolff, C. (1734) *Psychologia rationalis, methodo scientifica pertractata, qua ea, quae de anima humana indubia experientiae fide innotescunt, per essentiam et naturam animae explicantur, et ad intimiorem naturae ejusque autoris cognitionem profutura proponuntur (Rational Psychology, Treated According to the Scientific Method)*.(Referred to as the *Rational Psychology*.)

Wolff, C. (1736) *Theologia naturalis, methodo scientifica pertractata. Pars Prior, integrum Systema complectens, qua existentia et attributa Dei a posteriori demonstrantur (Natural Theology, Treated According to the Scientific Method. First Part of the Complete System, in Which the Existence and Attributes of God are Demonstrated a posteriori)*.(The first part of the *Natural Theology*.)

Wolff, C. (1737) *Theologia naturalis, methodo scientifica pertractata. Pars Posterior, qua existentia et attributa Dei ex notione entis perfectissimi et natura animae demonstrantur, et Atheismi, Deismi, Fatalismi, Naturalismi, Spinosismi, aliorumque de Deo errorum fundamenta subvertuntur (Natural Theology, Treated According to the Scientific Method. Second Part, in Which the Existence and Attributes of God are Demonstrated from the Notion of a Most Perfect Being and the Nature of the Soul, and the Foundations of Atheism, Deism, Fatalism, Naturalism, Spinozism and Other Errors Concerning God are Overthrown)*.(The second part of the *Natural Theology*.)

Wolff, C. (1738-9) *Philosophia practica universalis, methodo scientifica pertractata. Partes I-II (Universal Practical Philosophy, Treated According to the Scientific Method).*

Wolff, C. (1740-8) *Jus Naturae, methodo scientifica pertractatum. Partes I-VIII (Natural Law, Treated According to the Scientific Method)*.

Wolff, C. (1749) *Jus Gentium, methodo scientifica pertractatum, in quo jus gentium naturale ab eo, quod voluntarii, pactitii et consuetudinarii est, accurate distinguitur (Law Binding the World at Large, Treated According to the Scientific Method)*.

Wolff, C. (1750) *Institutiones juris naturae et gentium, in quibus ex ipsa hominis natura continuo nexu omnes obligationes et jura omnia deducuntur (Precepts of Natural Law and Law Binding the World at Large)*.

Wolff, C. (1750-3) *Philosophia moralis sive Ethica, methodo scientifica pertractata. Partes I-V (Moral Philosophy or Ethics, Treated According to the Scientific Method).*

Wolff, C. (1754-5) *Oeconomica, methodo scientifica pertractata. Partes I-II (Economics, Treated According to the Scientific Method)*.

3 Supplementary series

The supplementary series (39 separate volumes) contains: contemporaneous works on the history and influence of Wolff’s philosophy; some textbooks and other titles by Wolff’s students or followers (including Baumeister, Baumgarten, Frobesius, Gottsched, Stiebritz and Thümmig) who sought to popularize various aspects of Wolff’s thought; tracts by some of Wolff’s critics (such as Lange); and selected secondary works by modern writers (for example, Campo, École and Thomann) on Wolff’s thought.

Wollaston, William (1660-1724)

William Wollaston, a popular eighteenth-century English moral philosopher, is often grouped with Samuel Clarke as a staunch defender of the kind of moral rationalism that David Hume later opposed. Wollaston's project, as he describes it, is to find a rule to distinguish right actions from wrong. He complains that previous philosophers have either overlooked this task or proposed rules which are imprecise, incomplete or misleading. The rule he proposes is fidelity to truth. Actions, he argues, express propositions and so may be true or false. Moral actions express truths and immoral actions express falsehoods. He thinks this rule explains other widely held views about morality, for example, that we should live in accordance with nature, right reason or the will of God. His most remembered (and most misunderstood) claim is that an evildoer 'lives a lie'.

Wollaston was born at Coton-Clanford, England. He received an MA from Sidney Sussex College, Cambridge, in 1681, and was then assistant master in Birmingham Grammar School. In his late twenties he came into a large inheritance, married an heiress and retired to a life of study. His *The Religion of Nature Delineated* was first published privately in 1722.

More than a decade before *The Religion of Nature Delineated* appeared, Samuel Clarke had argued that right actions are 'fit' or appropriate to the real nature and relations of things. Evildoers, Clarke insists, by opposing the nature and reason of things, 'endeavour (as much in them lies) to make things be what they are not and cannot be' (1706: 613). This is as absurd as attempting to alter a mathematical truth. Wollaston constructs his whole moral theory around this idea. But, unlike Clarke, for whom the basic moral notions are fitness and unfitness, Wollaston seeks to reduce moral notions to truth and falsehood. True propositions 'express things as they are'; actions in general express propositions and so may be true or false. Whatever can be understood has meaning and, since actions can be understood, they have meaning. Actions, as Wollaston conceives of them, are simply our thoughts translated into deeds. Since we represent things with our actions, what we represent may be true or false. Immoral actions deny things to be what they are and so express falsehoods. If I take your property, I falsely declare it is mine. If I am ungrateful, I falsely declare I never received favours from you. The evildoer 'lives a lie' because his conduct, as Wollaston puts it, breathes untruths. As moral creatures, our aim should be to mirror truth, representing the way things are in our conduct. But Wollaston thinks that the reality we should strive to represent is our ordinary, everyday natural and social world, not a metaphysically independent moral order, as Clarke had maintained.

Wollaston thinks that the Stoic formula - follow nature - is correct if interpreted as enjoining us to treat things as being what they are and so according to truth (see Stoicism §15). He also argues that 'the way to happiness, and the practice of reason' are the same as 'a careful observation of truth'. Our nature is such that we aim at our own happiness. Not only is happiness our natural good, but we also have a duty to strive for our own and other people's happiness. Anticipating Jeremy Bentham, Wollaston defines happiness as the 'true quantity of pleasure': pleasures and pains may be measured in terms of their intensity and duration, and we are happy when the sum total of pleasures exceeds the sum total of pains. He argues that just as happiness cannot be achieved by anything that interferes with morality (truth), so the practice of truth (acting morally) cannot make a person unhappy. Morality and happiness are congruent - if not in this world, then in the afterlife.

Wollaston thinks his theory explains what we mean when we say that morality is a matter of following right reason. He characterizes reason as the power to survey and compare ideas and to make inferences from these. We discover truth by means of reason or, more precisely, right reason. So when our actions are in accord with right reason, they express truths. Immoral actions are contrary to reason because they assert falsehoods. The reports of our senses are true and may be acted upon as long as there is no reason against them. It is the nature of reason to command, Wollaston says; it enjoins, forbids or permits, and as rational creatures it should govern us. True happiness can be achieved only by pursuing means consistent with our rational nature; false pleasures are inconsistent with or destructive of it.

Wollaston concludes that the 'truest' definition of morality is 'the pursuit of happiness by the practice of truth and reason'. And when we act morally, he argues, we obey God's will. In rejecting the way things are, the evildoer is implicitly rebelling against God's will. The truths we should aim to mirror in our actions are God's truths. They

are natural, however, because we are able to grasp them by reason unaided by divine revelation. So there is, Wollaston says, such a thing as natural religion (see Natural theology).

Wollaston's attempt to reduce moral categories to truth and falsehood was criticized by subsequent philosophers, starting with David Hume (1739/40) and continuing today with John Mackie (1980) and Joel Feinberg (1977) (see Hume, D.). The problem these philosophers found with Wollaston's idea that immoral actions express falsehoods is that as a criterion of wrong actions it is circular. It is wrong for me to take your property, Wollaston says, because I falsely declare it to be mine, not yours. But if we ask why this is what my action means, the answer is that the fact that it is yours *means* that I should not steal it. In every case, the truth that is supposedly denied by a wrong action already has moral or normative content.

In the latter part of *The Religion*, Wollaston details our specific duties to God, others and ourselves. Anticipating Price and Kant, he thinks many duties command us to respect our own and other people's rational nature. He argues against attempts to persuade others without giving them reasons. To do so is to attempt to treat others as if they did not have reason.

CHARLOTTE R. BROWN

List of works

Wollaston, W. (1691) *On the Design of Part of the Book of Ecclesiastes, or the Unreasonableness of Men's Restless Contention for the Present Enjoyments, Represented in an English Poem*, printed privately.(Contains Wollaston's poem in heroic couplets inspired by chapters 1-4 of the Ecclesiastes, plus a paraphrase of these chapters, with notes on the paraphrase.)

Wollaston, W. (1722) *The Religion of Nature Delineated*, printed privately; repr. London: Samuel Palmer, 1724. The 'Life of Wollaston' is prefixed to the 6th edn, London, 1738. 10 more editions by 1750.(Wollaston's philosophically important work; argues that as moral creatures we should aim to mirror truth, representing the way things are in our conduct.)

References and further reading

Clarke, S. (1706) *A Discourse concerning the Unchangeable Obligations of Natural Religion, and the Truth and Certainty of the Christian Revelation*, in *The Works of Samuel Clarke*, vol. 2, New York: Garland, 1978. (Clarke defends a rationalist view of ethics. He argues that we come to see that actions are fit or unfit by rationally grasping the eternal and necessary relations holding between actions and situations. He also claims that reason by itself both obliges and motivates us to do what is fit.)

Feinberg, J. (1977) 'Wollaston and his Critics', *Journal of the History of Ideas* 38: 345-52.(A defence of Wollaston against his critics and their misinterpretations, although he agrees to some extent with Hume's main objections.)

Hume, D. (1739/40) *A Treatise of Human Nature*, ed. L.A. Selby-Bigge, Oxford: Clarendon Press, 1960, esp. book 3, part I, section 1, 461-3, and footnote.(Hume opposes Wollaston's moral theory, although at points he misinterprets it.)

Joynton, O. (1984) 'The Problem of Circularity in Wollaston's Moral Philosophy', *Journal of the History of Philosophy* 22: 435-43.(A recent attempt to defend Wollaston from the charge that his criterion of right action is circular or empty.)

Mackie, J.L. (1980) *Hume's Moral Theory*, London: Routledge & Kegan Paul, ch. 2.(Contains a brief but clear explanation of Wollaston's moral theory.)

Wollstonecraft, Mary (1759-97)

Wollstonecraft used the rationalist and egalitarian ideas of late eighteenth-century radical liberalism to attack the subjugation of women and to display its roots in the social construction of gender. Her political philosophy draws on Rousseau's philosophical anthropology, rational religion, and an original moral psychology which integrates reason and feeling in the production of virtue. Relations between men and women are corrupted by artificial gender distinctions, just as political relations are corrupted by artificial distinctions of rank, wealth and power. Conventional, artificial morality distinguishes between male and female virtue; true virtue is gender-neutral, consists in the imitation of God, and depends on the unimpeded development of natural faculties common to both sexes, including both reason and passion. Political justice and private virtue are interdependent: neither can advance without an advance in the other.

1 Life and influences

Mary Wollstonecraft was born into a declining middle-class family. Her father became a heavy drinker who beat his wife, and possibly his daughter too. Wollstonecraft had little formal education and early sought independence as a lady's companion, a schoolkeeper, and a governess, before rejecting such conventionally female occupations for the usually male one of translator and reviewer for *The Analytical Review*, a periodical founded by the dissenting publisher Joseph Johnson. She achieved fame with two political tracts: *A Vindication of the Rights of Men* (1790), attacking Edmund Burke's *Reflections on the Revolution in France* (1790) and*A Vindication of the Rights of Woman* (1792), her most substantial work (see Burke, E.). She also published educational works, a novel, an account of the French Revolution, and a travel book; a second novel was unfinished at her death. All the work published in her lifetime was written for money, the two *Vindications* extremely rapidly, without revision. While living in France to study the Revolution of 1789 at first hand she had an illegitimate daughter; after return to London and rejection by the child's father she made two attempts at suicide. She then resumed her journalistic career and formed a liaison with the political philosopher William Godwin, whom she married on becoming pregnant with a second daughter (later to become Mary Shelley). She died of complications following childbirth. Wollstonecraft seems to have been influenced chiefly by the eighteenth-century culture of sensibility, the educational theories of Locke and Catherine Macaulay, the dissenting, 'enlightened', politically radical circles round Joseph Johnson and Richard Price, who lived near the school she kept in Newington Green, and by wide and miscellaneous reading, particularly of Rousseau and Burke, opposition to whom formed her understanding of her own experience.

2 Wollstonecraft and philosophy

Wollstonecraft was not a systematic political philosopher aiming primarily at theoretical rigour, but something more like a *philosophe* as defined in Diderot's *Encyclopedie* (see Diderot, D. §1) For the *philosophe*, reasoning consisted in speculative generalization from experience, applied to the social issues of the day with an eye to practical improvement. Wollstonecraft combined ideas drawn from a variety of Enlightenment philosophies, from contemporary science, and from prevailing political, cultural and social movements into an explanation and evaluation of the current condition of women, of the state of society, and of her personal and professional experience within it. Her object was a rational programme of reform; her political works use philosophy only incidentally, to support political polemic.

Though this political polemic uses the language of liberalism, its philosophical foundations are, first, a speculative anthropology which distinguishes between natural and artificial human attributes, assigns most of human development to environmental influences, and expects progressive human improvement in morality and civilization; and second, a moral philosophy and psychology inspired by personal experience, current theories of the nervous system, and the suggestions of rational religion about the purpose of human life. This philosophical moral psychology achieved only fragmentary expression in Wollstonecraft's political works, but its outlines are fairly clear from her educational, fictional and travel writings.

3 Political philosophy

For Wollstonecraft, human beings were created to perfect their nature as rational and moral beings (see

Perfectionism). Natural humanity is not unsocialized humanity, as in Rousseau, but humanity freely developing its capacity for self-improvement, which includes the capacity for socialization. The function of society is further improvement of humankind. Social and political arrangements which thwart or fail to recognize this corrupt human nature.

Eighteenth-century society and politics are corrupted by artificial distinctions of rank (such as the aristocracy), the products of historical accident, which impede the development of all ranks towards human perfection; relations between the sexes are similarly corrupted by artificial distinctions of character and capability, such as the association of reason and moral strength with men, and feeling or sensibility and moral weakness with women. These artificial distinctions impede the development of both sexes towards full flowering of their human faculties.

Such corrupted environmental influences produce social injustice, along with vice in the aristocracy and brutish insensibility in the poor; the best hope of virtue lies with the middle classes. But even among these, artificial rank and gender distinctions are maintained by factitious interests such as social snobbery, male interest in the reduction of women to docile sexual objects, and female enjoyment of the opportunity this affords for sexual tyranny over men.

Thus the effect of artificial distinctions on social relations and public and private morality is, in the public sphere, political tyranny, social enmity, and a distorted conventional morality assigning different virtues to the two sexes; in the private sphere, domestic tyranny and the degradation of both male and female nature, to the detriment of physical health, moral development and parenthood.

The remedy is the abolition of artificial distinctions through political and social reform and the education of potential future citizens of both sexes into a radically revised, gender-neutral morality, based on religious but rationally derived principles. This new morality will redescribe conventionally gendered and sexualized virtues such as courage and modesty in forms applicable to both sexes, enabling women to become independent moral agents and rational wives and mothers.

Moral re-education, however, will be effective only in a context of gradual institutional, cultural and political evolution towards a republican meritocracy. Political revolution without moral evolution is dangerous (though it may sometimes be necessary as the lesser evil), since individual and social moral development are interdependent; private virtue will be difficult and therefore rare unless supported by the appropriate social and political structures, which will in turn be unstable without private virtue. For instance, the destructive passions aroused by oppression are likely to wreak havoc if released from social and political control before development of the capacity for rational management of the passions in the oppressed. Hence the later excesses of the initially benign and rational French Revolution of 1789.

4 Moral philosophy

The purpose of human life is perfection of human faculties in the imitation of God, who is moral perfection; however human perfection can be achieved only beyond the grave. In this life imitation of God consists in virtue, that is, acting autonomously from moral principle derived by reason from the attributes of God. Moral principles are not specified, but the supreme principle seems to be universal benevolence, conjoined with or entailing a principle of justice; God’s benevolence can be inferred from the convenient arrangements for his creatures manifested in nature. Benevolence prompted by sympathy for particular cases is a juvenile precursor, perhaps a precondition, of rational, adult morality motivated by principled universal benevolence.

5 Moral psychology

Moral development towards principled action depends on adequate development of the appropriate faculties, namely imagination, passion and reason, whose joint function is to reveal the true end of human life. Human beings come into the world endowed with appetite and the capacity to develop these higher faculties, though capacities vary with sensibility and development may be impeded by mistaken upbringing. Appetite, whose function is to preserve the body, proposes merely sensual, achievable objects of desire; imagination proposes ideal objects which make possible desire for something beyond the physically attainable. Such desires spring from the passions (fear, anger, love and so on), whose function is to elevate the mind. Sensibility (nervous sensitivity) is, or is linked to, capacity for imagination and passion.

Reason is developed by reflecting on efforts, especially frustrated efforts, to satisfy the passions and appetites. The reason which recognizes the function of the appetites, and tempers their satisfaction accordingly, is prudence; temperately satisfied appetite is earthly or animal happiness. The reason which recognizes the function of the passions, whose natural outcome is discontent, identifies the true end of human life, namely moral perfection or likeness to God; it produces virtue by transforming passionate desire into desire for perfection as the only object which can satisfy it. Attainment of perfection is true human happiness, which is impossible in this life.

Since the development of virtue depends on reason's interaction with the appetites and passions, virtue is not served by premature or inappropriate attempts to curb or stifle these. Rather, social conventions and education which restrict the activities and aspirations of women prevent the development of both reason and virtue, thereby justifying and reinforcing conventional gender roles. Conventional female education, by encouraging attention to sensory attractions, and instilling outward propriety instead of virtue, discourages development of the higher functions of imagination and passion, thus depriving an already weakened reason of opportunities to acquire knowledge of the true end of human life, and hence adult virtue.

List of works

Wollstonecraft, M. (1989) *The Works of Mary Wollstonecraft*, ed. J. Todd and M. Butler, London: William Pickering, 7 vols.(Contains all of Wollstonecraft's works, which are listed individually below.)

Wollstonecraft, M. (1787) *Thoughts on the Education of Daughters: with Reflections on Female Conduct, in the More Important Duties of Life*, in *The Works of Mary Wollstonecraft*, London: William Pickering, vol. 4, 1989.(Wollestonecraft's first published work; a handbook on female education probably based on her own practical experience.)

Wollstonecraft, M.(1788) *Mary: a Fiction*, in *The Works of Mary Wollstonecraft*, London: William Pickering, vol. 1, 1989.(A novel of ideas written to show 'that a genius will educate itself'; illustrates Wollstonecraft's early view of the course of ideal moral development, of the disadvantages of marriage for women, and of what would constitute an acceptable female social role.)

Wollstonecraft, M. (1788) *Original Stories from Real Life: With Conversations Calculated to Regulate the Affections and Form the Mind to Truth and Goodness*, in *The Works of Mary Wollstonecraft*, London: William Pickering, vol. 4, 1989.(A children's storybook carefully designed to promote moral development; the most detailed working-out of Wollstonecraft's views on moral education.)

Wollstonecraft, M. (1790) *A Vindication of the Rights of Men, in a Letter to the Right Honourable Edmund Burke*, in *The Works of Mary Wollstonecraft*, London: William Pickering, vol. 5, 1989.(An impassioned defence, by appeal to a rationalist as opposed to a sentimentalist moral philosophy, of Price's welcome of the French Revolution against Burke's attack; lays the foundation for Wollstonecraft's feminist politics.)

Wollstonecraft, M. (1792) *A Vindication of the Rights of Woman with Strictures on Moral and Political Subjects*, in *The Works of Mary Wollstonecraft*, London: William Pickering, vol. 5, 1989.(Attacks conventional female education, morality and gender role as presented by various contemporary authors of educational and conduct books, principally by Rousseau in Émile.)

Wollstonecraft, M. (1794) *An Historical and Moral View of the Origin and Progress of the French Revolution; and the Effect it has produced within Europe*, in *The Works of Mary Wollstonecraft*, London: William Pickering, vol. 6, 1989.(Wollstonecraft's reaction to the increasing violence of the French Revolution; historically derivative but useful for signs of development in her political thought.)

Wollstonecraft, M. (1796) *Letters Written During a Short Residence in Sweden, Norway, and Denmark*, in *The Works of Mary Wollstonecraft*, London: William Pickering, vol. 6, 1989.(Provide probably the most accessible introduction to Wollstonecraft's thought; they suggest a movement away from rationalism towards a greater interest in imagination and sensibility under the impact of personal experience.)

Wollstonecraft, M. (1798) *The Wrongs of Woman, or Maria*, in W. Godwin (ed.) *Posthumous Works of the Author of A Vindication of the Rights of Woman*, in *The Works of Mary Wollstonecraft*, London: William Pickering, vol. 1, 1989.(Unfinished; her first engagement with the wrongs of lower-class women; suggests that her earlier political and moral ideas, particularly on sensibility, were in a state of constant flux.)

Wollstonecraft, M. (1979) *Collected Letters of Mary Wollstonecraft*, ed. R. Wardle, Ithaca, NY: Cornell University Press.(Useful for following the development of Wollstonecraft's self-conception; also one of the few sources of knowledge of what she read.)

Wônch’ūk (613-96)

Wônch’ūk, a Korean monk-scholar, was head of the Ximing Monastery in Tang China. Neglected by history, research has now recovered this prolific writer, whose commentaries on Yogācāra texts influenced later Buddhist scholars in China and also in Tibet, notably Tsong kha pa.

The *Prajñāpāramitā-sūtras* and the *Samdhinirmocana-sūtra* are scriptures of Mādhyamika and Yogācāra Buddhism respectively. Xuanzang (596-664) introduced Yogācāra to China after having studied at NālandāUniversity, the bastion of Yogācāra in India. Returning to China with voluminous Sanskrit manuscripts, he presided over the Imperial translation project at Changan.

Wônch’ūk, Xuanzang’s colleague and critic, wrote an extensive commentary on the *Samdhinirmocana-sūtra*, ‘Explication of the Underlying Meaning’ which is extant today. One of the main points at issue is that while Mādhyamika declares that ‘dependently co-originated things’ do not have an unchanging intrinsic nature at all, Yogācāra insists on some real basis for these occurrences. Citing the theory of ‘three natures’ (*svabhāvatraya*), Xuanzang’s disciple Ji (632-82) simply asserts the superiority of the *Samdhinirmocana-sūtra* over the *Prajñāpāramitā-sūtras*’ ‘two truths’ (*satya dvaya*) theory. Wônch’ūk, however, unfolds a more careful investigation by claiming that Mādhyamika and Yogācāra are not competitors, but are in fact complementary schools. The *Prajñāpāramitā-sūtras*, for example, also contain the ‘three natures’ theory.

Wônch’ūk had an influence on Tibetan Buddhism as well. In the ninth century, Chos grub was ordered by a Tibetan king to translate Wônch’ūk’s commentary on the *Samdhinirmocana-sūtra* into Tibetan. Later, Tsong kha pa (1357-1419) followed Wônch’ūk’s methodology in his magnum opus *Drang nges legs bshad snying po (The Essence of True Eloquence)*. Here he quotes Wônch’ūk’s commentary on the *Samdhinirmocana-sūtra* extensively.

Yogācāra provides a religio-psychological analysis of the structure of mental activity by charting the path between consciousness and the dynamic unconscious, that is, between *manas* and *ālaya-vijñāna* (seventh and eighth consciousness) (see Buddhism, Yogācāra School of). Paramārtha (499-569) had posited the ninth consciousness as pure cognition. Wônch’ūk refutes this view in detail in his commentary on the *Samdhinirmocana-sūtra*. Tsong kha pa in turn uses the same argument critically in his work, *Yid dang kun Gzhi*.

Ji forced Xuanzang to make a selective translation entitled *Ren weishi lun (Treatise on the Proof of Representation Only)*, gleaned from the Indian commentaries of the *Trim’sikā (Thirty Verses)*. Although Wônch’ūk, along with the other disciples, was excluded from this project, he wrote his own commentary on this work, expressing many views divergent from those of Ji. Some pages of this lost work can be recovered from the rebuttals of Wônch’ūk’s commentaries made by Ji’s disciples.

While Ji became the systematizer of the Faxiang or *Yuishiki Hossō* school in Japan, Wônch’ūk’s fate was bleak. Even so, he was revered ‘as a living Buddha’ by the Empress Wu, who refused the request of a Silla king to send him home. But in the *Biographies of the Eminent Monks of the Song*, Wônch’ūk is described as being of obscure origin and of clever but dubious character. The truth is suggested by the following eulogy by his country man, Ch’oe:

Which ever translation of a *sūtra* it might be, he always
presided over that endeavour:
What ever commentary it might be, he always had something
unique to say:
Whenever he sought seclusion, he always attained inspiration:
To whomever he gave lectures on the Dharma,
he always reached everyone.

Wônhyo (617-86)

Wônhyo is one of the most important figures in Korean Buddhism, and a significant influence on the development of East Asian Buddhism in general. His lifework was the reconciliation of ideological conflicts among the various Buddhist schools. His goal was to create an all-inclusive, non-sectarian Buddhist doctrine. To do this he utilized the all-embracing, systematic metaphysics of the Hwaôm school of Buddhism, deriving both a guiding theoretical principle - hwajaeng *or 'the harmonization of all disputes' - and a powerful dialectical method for the examination of Buddhist doctrinal conflicts.*

Born in the Korean village of Puljich'on, not far from present-day Kyôngju, Wônhyo became a Buddhist monk at an early age and was a prolific writer, composing over one hundred books in 240 rolls. However, only twenty-three of these works survive, complete or in fragments. The most well-known of these are *Shimmun hwajaengnon (The Treatise on the Harmonization of all Disputes in Ten Chapters)*, *Daesûng kishillonso (The Commentaries on the Awakening of Faith in the Mahāyāna)*, *Kûmgang sammaegyông (The Treatise on the Vajrasamādhi-sūtra)* and *Yôlban'gyông jong'yo (The Essentials on the Nirvāna-sūtra).*

Wônhyo's dialectical method is based on the interrelation of two pairs of concepts, 'doctrine' (*chong*) and 'essence' (*yo*), as well as what he called the 'opening' (*kae*) and 'sealing' (*hap*) of Buddhist truth. Using these four key terms, he was able to place the various Buddhist ideologies of his day within a larger conceptual structure, demonstrating how points of conflict on the level of doctrine could be reconciled on the level of essence.

To Wônhyo, the term 'doctrine' referred to the expression of Buddhism's essentially ineffable, unitary truth through the differing conceptual vocabularies of the various Buddhist schools. When this unitary truth was 'opened' through philosophical discourse it became doctrine, accessible to the intellect for study and contemplation. Yet this 'opening of the one into the many', as Wônhyo termed it, was also the source of conflict and disagreement, for doctrinal truth was inherently self-limiting, defined by its own means of expression and therefore partial and biased.

In contrast, Wônhyo used the term 'essence' to refer back to the ineffable truth underlying all Buddhist ideology. He believed that doctrinal truth could be 'sealed' - that is, converted back to its unitary essence - beyond the scope of language or reason and therefore free of the limited perspective imposed by doctrine. He called this return to essence 'the sealing of the many into the one', and through it he sought to reconcile the various schools of Buddhist thought into a single, syncretic vision: *t'ong pulgyo*, 'the Buddhism of total interpenetration'.

The search for *t'ong pulgyo* has continued among Buddhist thinkers ever since, but Wônhyo's influence remains indelible. By combining the concepts of doctrine and essence with those of opening and sealing, he created a powerful interpretive tool for the examination of Buddhist texts, one that allowed him to apply the principle of *hwajaeng*, or 'harmonization', to a wide variety of theoretical conflicts. In so doing, he created the conceptual framework within which all subsequent discussion of *t'ong pulgyo* has taken place, up to and including the present day.

Work, philosophy of

Unlike play, work is activity that has to involve significant expenditure of effort and be directed toward some goal beyond enjoyment. The term 'work' is also used to signify an individual's occupation, the means whereby they gain their livelihood. In modern market economies individuals contract to work for other individuals on specified terms. Beyond noting this formal freedom to choose how one shall work, critics of market economies have maintained that one's occupation should be a realm of substantive freedom, in which work is freely chosen self-expression. Against this unalienated labour norm, others have held that the freedom of self-expression is one good among others that work can provide, such as lucrative pay, friendly social contact and the satisfaction of the self-support norm, and that none of these various work-related goods necessarily should have priority over others. Some philosophers place responsibility on society for providing opportunities for good work for all members of society; others hold that the responsibility for the quality of one's occupational life appropriately falls on each individual alone. Finally, some theorists of work emphasize that performance of hard work renders one deserving of property ownership (John Locke) or enhances one's spiritual development (Mahatma Gandhi).

1 Work versus play; work versus leisure

Work is effort directed at some goal other than enjoyment taken in the experience of putting forth the effort. In contrast, play is effort that is not aimed at any goal beyond the enjoyable experience of that very effort. Work and play seem to differ further in that a threshold level of effort must be put forth before an activity is properly called work, whereas play either involves a much lower threshold of effort or none at all. Tying my shoelaces is not typically work, even though the activity is goal-directed, because the effort involved is too slight. Effortlessly twiddling my shoelaces for fun qualifies as play even though hardly any effort is expended. Another example would be a spontaneous expression of joy by dancing a jig or of sorrow by singing a sad song. These expressive activities are not aimed at enjoyment, rather at expression of emotion, hence they do not qualify as play. But if effortless or close to effortless, they do not qualify as work either. Another example of an activity that is neither work nor play is lying on a beach in order to get a suntan. Again the effort constraint seems to be operative. Of course, if sunbathing can be described as involving expenditure of effort, say, because one's body is becoming hot or one is bored and one must actively overcome the desire to leave the beach by an effort of will, then in these circumstances sunbathing can be characterized as work.

In the Book of Genesis, God punishes Adam for sin by condemning him to unpleasant labour for his daily bread: 'By the sweat of your brow shall you live'. In order to meet their basic needs many, perhaps most, people throughout history have had to work in ways that are onerous and unpleasant, recalling Adam's curse. But work can give intrinsic satisfaction without ceasing to be work. Of persons engaged in work one can ask: (1) would they prefer to gain the goal they are seeking without working for it (if that is possible)?; and (2) would they wish to engage in the work activity for its enjoyment even if the goal they are seeking could be attained without the effort of work? An affirmative answer to the second question indicates that the work has the quality of a fusion of work and play. A negative answer to the first question indicates working is partly valued for its own sake, not just as a means to a further goal.

Work in the sense of goal-directed activity is opposed to play. In another sense of the term, work refers to what persons do in order to gain their livelihood. Time spent at work in this sense - work as occupation - is distinct from time spent at leisure - the free time in which individuals may do as they please and which is not spent at one's occupation. A day in the life of an individual may be divided into time spent at one's occupation, time spent in nightly rest, time spent in nonoccupational necessary drudgery such as household chores, and leisure or free time. This division is not exhaustive, however, because hours spent at childrearing do not comfortably fit into any of the categories just listed.

2 Work as occupation

With the rise of market economies work as occupation has become organized primarily by means of voluntary contracts among individuals who are not deemed to be under prior social obligation to engage in economic cooperation. Owners and managers of economic firms hire individuals to work as employees on specified terms. The tendency of market economies has been to generate greatly increased specialization of economic function and

task segmentation compared to earlier modes of economic organization. In the late eighteenth century Adam Smith analysed this process of division of labour and its economic consequences. He described a pin factory in which the making of pins was broken down into many small separate tasks, each small task performed over and over by an individual worker. This division of labour increases the productivity of labour; more is produced with less human labour input. Smith expressed the concern that repeated performance of a small boring task would ultimately dull the mental faculties of the workers.

Towards the middle of the nineteenth century Karl Marx (§4) propounded an ideal of unalienated labour and criticized the capitalist market economy of the day for subjecting ordinary workers, the bulk of the population, to grim lives that revolve around alienated labour. A capitalist market economy is one in which owners of capital establish firms that hire propertyless workers to produce goods for sale. In Marx's conception there are four aspects to alienated labour. One can be alienated from one's own activity of working, from the product one creates, from one's fellow human beings at work, and from one's true human nature. According to Marx, the worker in a capitalist factory is the epitome of an alienated labourer. A paradigm example of unalienated labour would be that of a creative artist, one who enjoys the freedom to produce art in one's own way and exercises this freedom in ways that are satisfying, controls the disposition of the art works so created, produces in such a way as to establish community with those directly affected by these economic transactions, and is motivated to create art by the desire to serve the human community (Alienation §§3-5).

The unalienated labour ideal raises many questions. One is whether fulfilment at work should be made available to all members of society as a matter of justice, or is better seen as a prize for which all may compete but which only especially meritorious individuals will win. If the norm of reducing alienated labour is deployed to criticize the institutions of society, the question arises how one should measure the progress of society in this respect. (For simplicity, this discussion assumes the possibility of precise measurement.) One might rate society by the average level of unalienated labour among those in the workforce, or one might rate society by the level of unalienated labour enjoyed by the member of society who is worst off in this respect, or by some other standard. In societies as we know them, access to desirable conditions of work is unevenly distributed between men and women and between members of favoured and disfavoured racial, ethnic and religious groups. There are the questions of how to characterize the good of desirable working conditions and what would count as a fair distribution of this good.

Jobs can evidently score higher or lower on the different dimensions of the unalienated labour norm, and one may wonder which dimensions are ethically more significant. If my occupation consists of menial work such as licking stamps for a worthy cause to which I am dedicated, my work life may be on the whole very meaningful, even if the work activity itself is unsatisfying. Alternatively, an individual's occupation might consist of challenging and interesting tasks performed for an enterprise that manufactures shoddy products of little true social utility. If one's workplace is a cooperative owned and managed by its workers, employment provides the opportunity for democratic participation in policy formation. A job that is regimented and unpleasant might provide high pay, which gives the jobholder freedom to carry out any of a wide variety of richly fulfilling plans of life. Jobs provide varied packages of benefits and burdens.

Work as occupation can provide benefits other than those that figure in the unalienated labour ideal. Lucrative pay, mentioned above, is one. Where most people subscribe to the social norm that each able-bodied adult should be self-supporting, supporting oneself by holding a job, even an undesirable job, earns the respect of other people and bolsters one's own self-esteem. There is a flip side to the coin of social recognition through jobholding, however. Since jobs vary greatly in prestige, holding an unprestigious job confers low status that can erode the jobholder's self-esteem. Another potential benefit from jobholding is that a regular job gives structure to one's life and organizes one's daily schedule. No doubt fully autonomous individuals could give a sensible shape to their lives without this external prop, but many of us are less than fully autonomous, and benefit from some degree of imposed order. Also, most jobs provide regular social contacts with workmates and perhaps with customers of one's firm. These contacts can be pleasant or abrasive, but usually there is at least the opportunity for friendly human interchange, and sometimes opportunities develop for deeper bonds of solidarity, friendship and mutual aid.

Regarding work as occupation, philosophers have argued for opposed views of the obligation of society. One is that the responsibility for each individual's work life belongs to that person alone; there is no positive obligation of society to ensure good work for all. A second view is that opportunities for decent employment should be made

available to all able-bodied adults. A third view is that the obligation of society is to provide each individual, so far as is feasible, freedom from the necessity to work by guaranteeing a basic minimum income to all individuals whether or not they participate in the workforce. The contrast between the second and third views reflects disagreement as to whether the necessity of working is a benefit or a burden and disagreement as to the validity of the social norm that each able-bodied adult is obligated to work for one's own livelihood.

3 Other perspectives

Philosophers have espoused perspectives on work different in kind from any of the views canvassed to this point. The seventeenth-century English philosopher John Locke emphasizes work as conferring entitlement to ownership of natural resources, particularly land, under appropriate conditions. According to Locke, an individual acquires ownership of nonscarce unowned land by labouring on it with the intent to establish ownership, and one sustains the right of ownership by continuing to work the land productively or by arranging for its productive use. Hard work renders an individual deserving of good fortune. Locke maintains that a more complex version of this story still holds true when land and other natural resources become scarce. The twentieth-century leader of the movement for the emancipation of India from colonial rule, Mahatma Gandhi, similarly holds that hard work for one's livelihood is a moral obligation and that working hard renders one deserving and morally virtuous. But in contrast to Locke, Gandhi upholds a norm of voluntary poverty and asceticism and recommends the discipline of hard work for its enhancement of the spiritual growth of the worker. In this spirit Gandhi urges the Indian people, and by implication all of us, to eschew modern industrial civilization and to earn our livelihood by hard work at pre-industrial, traditional forms of craft work.

Wróblewski, Jerzy (1926-90)

Jerzy Wróblewski was a leading representative of analytical legal theory in Poland in the second half of the twentieth century. Leon Petrażycki and the school of logical thought of Lwów and Warsaw provided his background inspiration. His approach to legal theory and legal science belongs, in philosophical terms, to minimalism, relativism and moderate reconstructivism.

Born in Vilnius, Wróblewski became involved as a partisan in guerrilla warfare during the German occupation of Poland, 1939-45, and was able to complete his education, taking a doctorate at the Jagiellonian University of Cracow, only after the defeat of Germany and the restoration of government in Poland. Immediately on graduation, he moved to Lódz to take up the chair in the theory of state and law there, remaining at that university (and serving a term as its Rector in the troubled years around 1980) until his death.

Wróblewski subdivides the tasks of legal theory into seven problem areas: the theory of the legal norm, the theory of interpretation of law, the theory of legal system, the theory of legal interpretation, the theory of the application of law, the theory of law-making, and the methodology of legal sciences. Norms he considered in linguistic terms, as part of natural language, giving a pragmatic analysis in terms of the speech acts from which they originate and through which they are interpreted and applied (see Norms, legal). His theory of legal system was Kelsenian in background, though he rejected transcendental reasoning and disputed the conception of legal order as purely dynamic, involving no possibility of logical derivation of conclusions from normative statements.

His most distinctive work was on the application of law, understood as the process of implementation of a legal norm by a state organ. His approach is marked by a painstaking and detailed analysis. He proposed what he called a ‘decisional’, as opposed to an informational or a functional, model of law-application. He analysed the problem of truth in judicial fact-finding on the basis of evidence, paying special attention to the variety of evidentiary facts presented to courts. In relation to the application of law, he disputed a narrow positivism that treats enacted law as sufficient in itself to control decision-making, and he argued for the necessity of referring to evaluations and values in this process; relevant sets of values he called the ‘ideology of application of the law’.

His interest in the rationality of legal processes extended to a concern with rationality in law-making and in the application of principles of legislative policy, using an instrumental conception of rationality based on the relationship between means and ends. As for methodology, he differentiated one-dimensional from multi-dimensional models of legal science. The former treat law exclusively as norm or as psychological fact or as social fact; the latter (favoured by Wróblewski) treat law as an ontologically and epistemologically complex phenomenon, and therefore approach the study of law using a variety of methods, techniques and conceptual apparatus derived from different social and mental sciences.

Wundt, Wilhelm (1832-1920)

The German philosopher, psychologist and physician Wilhelm Wundt founded the world's first psychological laboratory in Leipzig in 1879 - at a time when psychology was still generally regarded as a theoretical and institutional part of philosophy. This event typified his life's work and its reception in many respects. On the one hand Wundt tried to develop psychology as an independent science by defining its subject matter and methodology; on the other, he wanted to integrate psychology into the context of philosophy, cultural theory and history. With both attempts he acquired world fame and at the same time became a most controversial figure. Systematizing his approach, Wundt worked on a great amount of material in very different disciplines. He has been called the last philosophical 'polyhistor' in the tradition of Leibniz and Hegel, as well as the first modern scientist in psychology.

1 Life

Wundt was born in 1832 in Neckarau, near Mannheim, and died in 1920 in Großboten, near Leipzig. He studied medicine at the universities of Tübingen, Heidelberg and Berlin, and began his academic career as a research assistant of Johannes Müller and Emil du Bois-Reymond in Berlin. From 1857 to 1864 he was *Privatdozent* at the Physiological Institute in Heidelberg directed by Hermann von Helmholtz. Rejecting Helmholtz's materialism, Wundt's own physiological studies shifted to the theory of sense perception, which he conceived of as a deeply philosophical question. Furthermore, he began to lecture on anthropology, ethnography and natural history. During these Heidelberg years, Wundt changed from physiologist to psychologist, yet always orientated himself within a philosophical framework. After a professorship in inductive philosophy at Zürich, in 1875 he accepted a professorship in Leipzig, where he founded his famous *Institut für Experimentelle Psychologie*. Beginning as a purely private institute, it later became the point of departure for many international students who returned home to establish similar institutions. Wundt taught at Leipzig until his death, continuously developing and changing his system in a spirit of encyclopedic scholarship. Over the last twenty years of his life he worked out his *Völkerpsychologie*. As an old man he became the rector of Leipzig University and was accorded tremendous national and international recognition.

2 Philosophy, psychology and science

With Wundt, the psychological zeitgeist shifted from philosophy to science, yet, even as a scientist, Wundt never left philosophical ground. Beside his seminal studies in physiological psychology, he lectured and wrote on logic, ethics, epistemology and other traditional philosophical topics, drawing especially on Leibniz and Hegel, but also on Mill's methodology (see Mill, J.S.). It has often been overlooked that for Wundt himself 'experimental psychology' was only a particular way to tackle traditional philosophical issues - and to engender new ones. If he was himself an experimenter at heart, as Robinson notes, then he was surely the 'first philosophical psychologist spawned by experimental science' (1982: 129).

Although his *Physiological Psychology* was taken above all as a programme for experimental research, it also represented an attempt to resolve the mind-body problem. Investigating both physiological and mental phenomena, Wundt's basic intention was twofold: he wanted to overcome the traditional Cartesian dualism of *res extensa* and *res cogitans* without falling into materialistic monism. As he saw it, psychology studies particular events which cannot be reduced to a class of mere bodily events. Both physical and psychical processes exist 'side by side' but must conform to their own epistemological principles. Rather, historically and systematically, psychology draws upon these different approaches; its subject matter emerges at the point of contact of distinct epistemic spheres. Thus, Wundt's idea of psychophysical parallelism was a heuristic principle, not an objective law. The main distinction was not between mind and body, but between reasons and causes, that is, between forms of explanation adequate for different categories of events.

In calling the new discipline of this border region 'experimental psychology', Wundt wanted to place a major emphasis on the methodological characteristics by which he distinguished his approach from the traditional science of mind, which was based above all on introspection. Rejecting any idea of the mind as a separate spiritual or mental substance, Wundt believed it to be the totality of conscious experiences (and its partly unconscious emergence) at a given moment. He called this the 'actuality' of the mind.

Experiences, ideas and thoughts are active events - neither simple reactions nor things or impressions appearing in and disappearing from consciousness (as associationists and structuralists claimed). Will is the fundamental principle of mental activities. But there is no will without emotion. Inextricably interwoven, both intention and feeling organize the meaningful syntheses of all psychological events. Thus, Wundt called his conception of the mind 'voluntaristic', underlining the peculiar human quality of actively creating meanings.

Wundt designated the idea of a conscious focus of attention, which synthesizes the elements of experience and thought into larger units (*Gesamtvorstellungen*), the 'principle of creative resultants or synthesis'. This is closely linked to another key concept in Wundt's system: the concept of 'apperception'. Deriving from Leibniz and Kant, 'apperception' referred to the active synthesizing function of consciousness. Hence, it represented a central feature of higher mental activities, as it is responsible for all conscious constructions or wholes, such as thought, language, reasoning and judgment.

In adapting the methods of empirical, experimental and historical sciences to the questions of philosophy, Wundt wanted to create an integrated discipline of the mind. This was the content of his 'Heidelberg programme' of psychology which he only partly realized in the second half of his life in Leipzig (*Graumann 1980*). This programme consisted of: (1) the experimental study of human consciousness or mind; (2) the evolutionary history of mind; (3) comparative psychology (particularly dedicated to the analysis of ontogenetic and phylogenetic development).

Wundt's theory of the mind was a universal developmental theory. To understand the strong historic-genetical dimension of this conception (which for many decades had been widely ignored), one must take into account the influence of the two cultures Wundt wanted to fuse together: for the philosopher Wundt, the emphasis on cultural-historical development was a typical legacy of most German nineteenth-century philosophy since Hegel, Herder and the Enlightenment; for the physiologist and physician, the crucial event of those years - as it was for all life scientists - was the publication of Darwin's *Origin of Species* in 1859.

3 *Völkerpsychologie*

Wundt considered experimental psychology only as an elementary approach to the study of the mind. He rejected the idea that higher mental processes could be represented by a kind of mechanics of the mind parallel to physical mechanics. Physical causality (as investigated, for example, in the psychophysics of Gustav Fechner (§2)) is only a quite limited aspect of human psychology which, as a whole, is characterized by a qualitatively different causality: 'psychical causality'.

To understand fully the psychological causality of the mind, it is not enough to examine the isolated consciousness of an individual, because in reality this is always embedded in a cultural web. These cultural mediations between the individual and the world determine the characteristics of the human mind. Therefore, we must expand the merely analytical framework of the individual mind and conceive of it as the product of a multilayered development. Ontogeny, natural history and social history are interwoven processes which demand multidisciplinary study. Wundt called this study of cultural development '*Völkerpsychologie*'. (The translation 'folk psychology' is misleading; better would be 'cultural psychology' or 'historical psychology' - in fact, Wundt also used both these terms.)

Völkerpsychologie is the comparative study of the products of social life in different historical periods and cultures. Wundt focused on language, custom, ritual, institutions and collective representations such as myth, art and religion. The great importance given to language as the central mediation between the individual mind and a culturally meaningful context was reflected in his psycholinguistic theory.

Like the 'Heidelberg programme' of Wundt's early years, the cultural-historical programme of the Leipzig *Völkerpsychologie* must be seen against the background of the tradition of philosophy of mind in German Idealism (see German idealism). Wundt's thought was a Hegelian variant, as was the conception of *Geisteswissenschaften* of his contemporary Wilhelm Dilthey; while a few years later, Ernst Cassirer presented a Kantian variant in his *Philosophie der symbolischen Formen*.

Wundt believed that in order to complete individual psychology, the methodological spectrum had to be broadened. Like history, anthropology or psychopathology, *Völkerpsychologie* is based on the ability to immerse

oneself in an alien state of mind and various stages of the cultural evolution of human thought. In the ten volumes of *Völkerpsychologie*, Wundt outlined an initial methodology of 'participant observation' which he thought essential to all cultural psychology.

While many elements of *Völkerpsychologie* were developed in disciplines such as sociology, anthropology and cultural history, Wundt's approach did not play a major role in mainstream psychology or philosophy of mind. In the behaviourist movement especially, it was completely discarded. Only since the 1970s has a new orientation in philosophy and psychology towards the mind yielded a growing interest in the cultural and historical mediations of mental development and thus in Wundt's work (see Bruner 1990; Jahoda 1992).

Wyclif, John (*c.*1330-84)

John Wyclif was a logician, theologian and religious reformer. A Yorkshireman educated at Oxford, he was first prominent as a logician; he developed some technical notions of the Oxford Calculators, but reacted against their logic of terms to embrace with fervour the idea of the real existence of universal ideas. He expounded his view as a theologian, rejecting the notion of the annihilation of substance (including the eucharistic elements) and treating time as merely contingent. The proper understanding of universals became his touchstone of moral progress; treating scripture as a universal idea, he measured the value of human institutions, including the Church and its temporal property, by their conformity with its absolute truth. These views, though temporarily favoured by King Edward III, were condemned by Pope Gregory XI in 1377 and by the English ecclesiastical hierarchy in 1382, forcing him into retirement but leaving him the inspirer of a clandestine group of scholarly reformers, the Lollards.

1 Life

John Wyclif was born to a Richmondshire (Yorkshire) family about 1330 and ordained in 1351. He made his reputation as a logician and natural philosopher at Oxford. Though his earliest logical works and *De actibus animae (The Actions of the Soul)* were unremarkable, his distinctive ideas emerged from theological study, in the several tracts of his *Summa de ente (Summa on Being)* and especially in *De universalibus (On Universals)*, where he developed his distinctive theory of universals in logical terms, though not without theological opposition. Seeing the Bible as one such eternal idea in the mind of God and therefore an unchanging moral yardstick, he contrasted the ephemeral institutions of the Church with the absolute values instilled by scripture in the individual conscience, in *De civili dominio (On Civil Dominion)* and *De ecclesia (On the Church)*. These opinions made him numerous ecclesiastical enemies, while gaining him the temporary patronage of government and the lasting loyalty of a group of scholars. He went on to dismiss the doctrine of transubstantiation on logical grounds, an unorthodox view which forced him to leave Oxford for his Leicestershire living. In retirement, he produced a mass of repetitive controversial pamphlets and summaries. He inspired the Lollard scholars and preachers who supported him in translating the scriptures into English and in disseminating his ideas throughout England.

2 Contribution to logic

Wyclif's philosophical ideas were those of an accomplished logician inspired by a Platonizing religious vision. His contribution to logic is primarily found in the tracts published as *De logica (On Logic)*, written for theologians with a defective logical training. He expounded the logic of the Oxford Calculators, of whom Thomas Bradwardine, William Heytesbury and Richard Billingham were the most influential (see Oxford Calculators). Billingham in particular, whose lectures Wyclif may have attended in the 1350s, provided the basis for Wyclif's ideas of possible proofs of propositions. Wyclif proposed a fourfold division of proof: a priori, a posteriori, proof by reduction and proof *ab aequo*, that is, by definition and exposition or resolution of terms. This division was adopted and refined by later Oxford logicians (see Logic, medieval).

Wyclif also made a contribution to the understanding of insoluble propositions which approached the modern notion of semantic groundedness. Furthermore, he rejected the nearly unanimous view of contemporary logicians that there were real *continua*, such as time, maintaining instead that these consisted of discrete instants, points and so on (see Natural philosophy, medieval). He saw such abstract concepts, or universals, as real entities, indestructible ideas in the mind of God, rejecting the linguistic thinking of contemporary logicians, whom he came to dismiss in later works as 'sign-doctors' (see Language, medieval theories of).

3 Philosophical ideas

Wyclif took a distinct view in his most important philosophical work, *De universalibus*, on the real existence of universals, to which his approach was again that of a logician. He set out his view primarily as an analysis of predication: how could Socrates *be* a man, and how could man *be* a species? Predication involved the notions of identity and distinction; besides the traditional 'essential' distinctions of genus and species, he posited the 'real' distinction of entities with the same essence, like the persons of the Trinity, and the 'formal' distinction between the matter and substantial form of an individual, such as between God the Father and the divine nature. An

individual 'participated' in a number of universals, being the end of a chain of inherence. The predication of a universal could presuppose a real and not merely a linguistic relation: as smoke signifies fire, and fire is thus predicated of smoke, so a real universal could be predicated of an individual (see Universals).

It followed that if a real universal outside the accidents of time and space inhered in all substances, no substance could be destructible: God 'could not annihilate a creature without annihilating the whole created universe' (*De universalibus* 307), as such destruction would include the destruction of eternal intelligible being, a universal in which it inhered. Creatures subject to change and confined in place and time, being also ideas, must equally exist outside time, in the state Wyclif called *duratio*. Wyclif resolved the question of what distinguished two individuals in which the same universal inhered by positing a distinction in their different positions in time.

Wyclif's understanding of real universals seemed to him to resolve in an original way a great question of the schools, the relation of human free will (which he acknowledged like his contemporaries) to the perfection of divine foreknowledge. Though all human actions follow upon the will of God, still the unchanging will of God as to future contingent events may be determined by human volition at any moment. Since God's will is outside time, operating at once in the past and the future, events now may constitute causes determining God's will from the beginning of time. Human merit, therefore, may temporally, but not in principle, be prior to divine grace; grace must be necessary and eternal as it proceeded from God, and only contingent as it inhered in essences (see Eternity; Free will; Grace).

Some further, unorthodox theological consequences of real universals were more difficult to adopt, and Wyclif hesitated before embracing them. One clear consequence of his belief that substances could not be annihilated touched the eucharist. The doctrine of transubstantiation required that the elements, bread and wine, were annihilated and replaced by the body of Christ. Eventually, after attempting to reconcile orthodox doctrine with real universals, Wyclif rejected transubstantiation, maintaining that the sacramental elements remained in the consecrated host. This was a principal reason for the condemnation of his theology.

His view of universals, albeit couched in contemporary logical language, was at root a religious conviction formed under the Platonizing influence of Robert Grosseteste. Wyclif considered a proper understanding of universals the firm ground of moral progress, a prophylactic against moral relativism. Awareness of this marked a quantum leap (*gradus percipuus*) up the ladder of wisdom: 'error about universals is the cause of all the sin that reigns in the world' *De universalibus* 175-7). His convictions gave him the strength to pursue their moral and political implications.

4 Scripture and human dominion

From about 1374, while Wyclif worked out what he saw as the moral and practical consequences of his ideas, he propagated them in countless lectures, pamphlets and sermons, and gathered disciples who carried out a scheme for an English text of the scriptures. He had already identified the Bible as a real universal. Faced with the problem of a corrupt text, he explained that 'intellection in the mind is more truly scripture than lines on a membrane' (*De veritate sacrae scripturae* (1377-8), i. 189). Scripture was a moral absolute, but operated internally as a guide, allowing for no earthly authority to interpret it.

On this basis, he approached the currently discussed question of divine and human dominion. The latter was merely contingent and relative, depending on its conformity with God's will in each individual case; there was no independent right of dominion on the part of ecclesiastical or secular authorities. Lordship was merely stewardship, and depended upon the state of grace of its wielder. Wyclif strongly emphasized the implications for the temporal possessions of the clergy; the consequences for civil government were only gradually recognized. His subjective political philosophy thus attracted some superficial support from the English government, but was explicitly condemned by successive church authorities. Together with his views on transubstantiation, it ensured his removal from Oxford and confinement to his role as the inspirer of a body of evangelizers.

5 Influence

As the inspirer of the Wycliffite English bible and of a programme of disendowment and purification of devotion, Wyclif had great influence in England, in Bohemia through the Hussite reformers (see Hus, J.) and throughout Protestant Europe in the sixteenth century. His logic circulated with that of other Oxford logicians in

fifteenth-century Italy, as a set of texts for instruction. His more general philosophical works were much read in England up to the mid-fifteenth century, and played a subordinate role in the corpus of his writings copied in Bohemia; but they were forgotten in the general disfavour which the logic of the schools attracted after 1500, and when Wyclif's works began to be republished in the late nineteenth century, their importance and originality was not recognized. Substantial sections are still unpublished, including the important tract *De tempore*. However the significance of their contents was appreciated by several scholars, beginning with M.H. Dziewicki and S. Harrison Thomson (1931), who each edited some of his philosophical works, and by J.A. Robson (1961), Anthony Kenny (1985, 1986) and Paul V. Spade (1975), who all noted original features of his thought. Further study and editions of the remaining philosophical works are still required.

Xenocrates (396-314 BC)

The Greek philosopher Xenocrates was the third head of the Platonic Academy. Like his predecessor Speusippus, he further developed Plato's philosophy, but along more orthodox lines. Indeed, Xenocrates contributed much to the formalization of Plato's philosophy into dogma. Starting from a metaphysical system of Monad and Dyad, the former being a self-contemplating intellect on the Aristotelian model and the latter a material principle, he systematically derived the rest of creation, postulating first the generation of number, and then soul, defined as 'self-moving number'. He is notable for a tendency towards triadic divisions of the universe, and a developed theory of daemons. He was probably responsible for the first definitive edition of Plato's works.

1 Life and works

Xenocrates was a native of Chalcedon, on the Bosporus. He succeeded to the headship of the Platonic Academy in 339 BC, on the death of Speusippus (see Academy). He had been a member of the Academy since early youth, and had accompanied Plato to Sicily, presumably on Plato's second or third visit (see Plato §1). He continued in the headship to his death, when he was succeeded by Polemo.

Xenocrates is credited with being the first to distinguish formally between the three branches of philosophy that comprise physics (including metaphysics), ethics (including politics) and logic (fr. 1 Heinze, fr. 82 Isnardi Parente; Xenocrates' fragments appear in two separate editions, cited below as 'H' and 'IP', respectively) - although Aristotle does seem to make the distinction in *Topics* I 14. Seventy-six works of his are listed by the biographer Diogenes Laertius, covering all of these fields, the most important being *On Nature* in six volumes, *On Wisdom* (*sophia*) also in six books, *On Being*, *On Fate*, *On Virtue*, *On Forms*, *On the Gods*, *On the Soul*, *On the Good*, *Solution of Logical Problems* (ten volumes) and *On Genera and Species*. He also wrote on Pythagoreans and on numbers, which indicates a continuation of Speusippus' interest in these areas. All of his works have perished, apart from a short extract from his *Life of Plato* (fr. 53 H, frs 264-6 IP), attributing to Plato a doctrine of five (instead of the usual four) elements, on the basis of an interpretation of the *Timaeus*.

2 Metaphysics and cosmology

As first principles, like Plato and Speusippus, Xenocrates postulated a pair, which he seems to have termed Monad and Dyad (fr. 15 H, fr. 213 IP), the latter a principle of multiplicity and unlimitedness (fr. 68 H, fr. 188 IP). Xenocrates also identifies his second principle as matter (fr. 28 H, fr. 101 IP). What we seem to have here is a 'female' principle manifesting itself sequentially at various levels of reality, rather like that of Speusippus. As regards the Monad, however, Xenocrates differs significantly from Speusippus in declaring it to be an intellect, or *nous* (fr. 16 H, fr. 214 IP) - possibly in reaction to Aristotle's criticisms of Speusippus. At any rate, the essentially Aristotelian concept of a self-contemplating divine intellect is that which is dominant in all subsequent 'official' Platonism up to Plotinus.

Another point of difference between Xenocrates and his predecessors seems, if we accept the view of Theophrastus (*Metaphysics* 6a23-), to have been the comprehensiveness of his attempt to derive the totality of existence from his first principles. The doxographic report in fragment 15 H (fr. 213 IP) tends to confirm this, although it contains problems: it is not even clear whether Xenocrates intends his Monad to be transcendent or immanent, while the Dyad, unless the text is to be amended, is presented as identical with the world-soul, which it should not be, since we learn from Plutarch (*On the Creation of Soul* 1012d-e) that for Xenocrates the world-soul is the product of Monad and Dyad.

Xenocrates first derived number from the Monad and Dyad, then point, line, plane and solid from number - or perhaps from the first four numbers, the Pythagorean *tetraktys* (see Pythagoreanism §2). This involved him in the troublesome doctrine of indivisible lines (and planes and solids), which is criticized in the pseudo-Aristotelian work *On Indivisible Lines* (frs 41-9 H, frs 123-47 IP) (see Atomism, ancient).

As regards the Platonic theory of Forms, Xenocrates is reported as going the opposite way to Speusippus, abandoning the 'mathematicals' while Speusippus dismissed the Platonic ideal numbers, but this is doubtless an oversimplification. Aristotle asserts that Xenocrates postulated only Forms, which he identified with numbers (fr. 34 H, frs 103-12 IP). Although mathematical entities, the Forms are still causes of sensible particulars. Xenocrates

is on record (fr. 30 H, fr. 94 IP) as defining a Form as 'the paradigmatic cause of regular natural phenomena', a definition intended to rule out forms of artificial objects and things contrary to nature (*ta para physin*). This became the standard definition in later Platonism. As to the location of the Forms, since the Monad is an intellect, and an intellect must think, it seems not unreasonable to trace the later Platonic doctrine of the Forms as the thoughts of god back to Xenocrates, but we have no evidence on this point (see Platonism, Early and Middle (§3) for a more detailed discussion of Form-numbers).

Soul he defined as 'a self-moving number' (fr. 60 H, frs. 176-87 IP). We learn from Plutarch's *On the Creation of Soul* that Xenocrates gave a description of the formation of the soul that was simply a development of the creation of number (and thus of Forms) (fr. 68 H, fr. 188 IP). Basing himself on Plato's account of the soul's components in *Timaeus*, he takes the 'indivisible substance' as the Monad and the 'divisible substance' as the Dyad. Their mixture results in number, but not yet soul. It lacks 'motion', the defining characteristic of soul. This is supplied by the elements of sameness and otherness, the former representing stability, the latter motion and change.

A notable feature of Xenocrates' physics is his triadic division of reality into intelligible, sensible and 'opinable' realms, this last comprising the heavens, the contents of which are visible, but their nature only cognizable by reasoning (fr. 5 H, fr. 83 IP). A rather different, and more peculiar, triadic division is reported by Plutarch (fr. 56 H, fr. 61 IP), involving different degrees of 'density', combined with various of the four elements.

Xenocrates had a developed doctrine of daemons (see Platonism, Early and Middle §7), about which we learn much, again, from Plutarch (fr. 23 H, frs 222-3 IP). Again, mathematics is involved, since daemons are declared analogous to isosceles triangles, intermediate between the equilateral triangles of the gods and the scalene triangles proper to humanity. He postulated evil daemons as well as good, as an explanation for all the nasty aspects of religion such as ritual obscenity and human sacrifice (fr. 25 H, frs 229-30 IP).

3 Ethics and logic

On ethics Xenocrates wrote a good deal, but not much that is distinctive survives. He defined happiness (see Eudaimonia) as 'the possession of the excellence (*arēte*) proper to us, and of the power subservient to it' (fr. 77 H, fr. 232 IP). He agreed with Aristotle about the necessity of a modicum of bodily and external goods (this constituting the 'power' of the definition). He anticipated the Stoics by identifying the first principles of happiness as 'the primary natural instincts' (*ta prōta kata physin*) (frs 78-9 H, frs 233-4 IP) (see Stoicism §15-17).

In logic, he still maintained the Platonic system of 'division', together with the basic categories of absolute and relative (fr. 12 H, fr. 95 IP), rejecting the Aristotelian ten categories (see Aristotle §7). In epistemology he recognized three levels of cognition, corresponding to the three levels of the universe (fr. 5 H, fr. 83 IP).

Xenophanes (*c*.570-*c*.478 BC)

Xenophanes was a philosophically minded poet who lived in various cities of ancient Greece. He is best remembered for an early comment on the limits of knowledge, a critique of anthropomorphism in religion and an advance towards monotheism. The surviving fragments of his poems span a wide range of topics, from proper behaviour at symposia and the measures of personal excellence to the nature of the divine, the forces that rule nature and how much can be discovered by mortals concerning matters in either realm. Both Plato and Aristotle characterized him as the founder of Eleatic philosophy, a view echoed in the pseudo-Aristotelian treatise, On Melissus, Xenophanes and Gorgias*, and in ancient doxographical summaries. But in many of his poems Xenophanes speaks as a civic counsellor and inquirer into nature in the tradition of the philosopher-scientists of Miletus. While his one, unmoving, whole and eternal divinity bears some resemblance to Parmenides' 'being', in other teachings he anticipates the views of Heraclitus and Empedocles. His comments on divine perfection, the limited utility of the victorious athlete and the need to restrict poetic expression all foreshadow views expressed by Plato in the* Republic*.*

1 Life and writings

Xenophanes is reported to have been the son of Dexios (or Dexinos or Orthomenes) of Colophon. In fragment 8 he claims to have lived in Colophon for twenty-five years before leaving to spend the next sixty-seven as a travelling bard 'tossing about the Greek land'. If we tie his departure from Colophon to the conquest of Ionia by Harpagus the Mede (in 546/5 BC) and accept the report of the historian Timaeus that Xenophanes lived in the reign of Hieron of Syracuse (478-467 BC), we may date his life to the years 570-478 BC.

Ancient reports of his contacts with other philosophers are few and inconclusive, but the reference in fragment 7 to a puppy which possessed the soul of a friend shows some awareness of Pythagorean teachings (see Pythagoreanism §3) and the remarks about earth, sun, sea, waters and rainbow in fragments 27-32 display an interest in matters investigated by the Milesians. Herodotus (I 74) reports Xenophanes' 'admiration' or 'wonder' (or perhaps 'amazement') regarding Thales' successful prediction of a solar eclipse (see Thales §1); Heraclitus' fragment 40 disparages him as a (mere) polymath; and Empedocles' fragment 39 challenges the view of the earth's 'unlimited' depths expressed in Xenophanes' fragment 28.

Xenophanes wrote in verse, a fact which reflects both his chosen profession and an age that drew no sharp distinction between poet, sage and teacher. Most of his poems eschew complex argument in favour of simple and emphatic dissent (the Greek words *de* and *alla* - both meaning 'but' - appear often), but fragments 2, 15, 30, 34 and 38 employ hypothetical suppositions or 'thought experiments' to establish unnoticed contrasts and connections, and the different aspects of his teachings can be placed within a coherent overall scheme. He is the first Greek philosopher for whom an appreciable body of work has survived, but his difficult terminology and phrasing, along with the conflicting ancient testimonia, have spawned radically different interpretations of his teachings and sharply divergent appraisals of his importance as a thinker.

2 Social criticism

The material contained in five fragments (1, 5, 8, 22 and 45) appears to have been composed for performance at symposia; seven others (2, 3, 4, 6, 7, 20 and 21) mention individuals or issues suitable for discussion in such a setting. Although often considered of little philosophical interest, these verses establish Xenophanes in a role subsequently assumed by Heraclitus and Socrates - the philosopher as civic gadfly.

The detailed description of a wholesome banquet scene with which fragment 1 opens prepares the way for a concluding injunction to a parallel purity in speech and conduct, particularly in the songs sung on such festive occasions. Xenophanes' disapproval of the old stories of divine warfare and factional strife reflects the concern for the wellbeing of the city evident in his criticisms of the honours lavished on athletes (fr. 2), the luxurious lifestyle of the citizens of old Colophon (fr. 3), the stories told about the gods by Homer and Hesiod (frs 11-12) and Homer's exalted status as the educator of Greece (fr. 10). His description of himself as a travelling counsellor (frs 8 and 45), a reference to the Lydians as the inventors of coinage (fr. 4), a preferred method of wine-mixing (fr. 5) and a listing of topics suitable for discussion at symposia (fr. 22) reflect similar concerns.

Since Xenophanes lived before the time of the Sophists he had nothing to say on the many questions their sceptical and relativist views generated. Nevertheless, a number of his teachings - that the divine is incapable of immoral conduct, that wealth and luxury pose a threat to the survival of the city, that a civic good outweighs any individual good, and that the songs sung by poets must be censored for the sake of the city’s welfare - survive in the work of Plato and Aristotle.

3 Religious views

Since ’greatness’ for a Greek god typically meant ’greatness in power and honour’ (Homer, *Iliad* II 412 and *Odyssey* V 4), Xenophanes’ assertion that ’one god is greatest among gods and men’ (fr. 23) helps to explain a number of his remarks about god’s powers and perfections: god’s capacity to shake ’all things’ simply by thinking (fr. 25); the ’whole’ character of god’s thinking and perceiving (fr. 24); the degree of seemliness appropriate to god (fr. 26); various denials of divine births, bodies and voices (frs 14 and 23); the call to honour the gods (fr. 1); and the repudiation of the poets’ tales (frs 1, 11 and 12). While the ’one greatest god’ of Xenophanes embodies some qualities popularly ascribed to Zeus, his unchanging and isolated form of existence (according to frs 25 and 26) rules out many other popular beliefs - for example, that a god might reside in pine branches (fr. 17), that gods intimate their intentions to mortals (fr. 18, A52); and that the sun, sea, earth, moon and rainbow are themselves gods or goddesses (frs 30-32, A39, 41-6).

Xenophanes’ repeated use of the plural ’gods’ has sparked debate concerning the depth of his monotheism. Fragment 23 speaks merely of one *greatest* god, and it was the immoral conduct of Homer’s and Hesiod’s gods that prompted Xenophanes’ criticism, not their plurality. We may also reasonably doubt ’whether a convinced monotheist in an unreceptive polytheistic society would cloud the issue by a mention of plural gods which is at best ambiguous in the very context in which he is stating his revolutionary view’ (Stokes 1971: 76).

Fragment 16 asserts that ’Ethiopians [say that their gods are] snub-nosed and black/Thracians [that theirs are] blue-eyed and red-haired’ (similarly, fr. 15: ’… if horses or oxen or lions had hands… horses would draw the figures of the gods as similar to horses and the oxen as similar to oxen… ’). It is not clear whether these famous remarks were meant to refute all anthropomorphic conceptions of the gods, or merely to explain how the gods came to have the qualities popularly ascribed to them (that is, rightly or wrongly, people always assume that the gods are like themselves). Fragment 34 concedes that even unintelligent opinion occasionally enshrines the truth (see §5) and, since a different bodily feature is mentioned in each case, fragment 16 does not actually point to inconsistencies in popular views of the gods.

Later doxographical summaries report that Xenophanes identified god with the entire (spherical) physical universe, but many scholars consider the doxographers’ accounts to have been inspired mainly by Plato’s and Aristotle’s loose identifications of Xenophanes as the founder of Eleatic thought, and the practice of crediting the putative founder of a school with discoveries made by his followers.

4 Natural science

The seriousness of Xenophanes’ interest in natural science has been generally discounted, in part as a consequence of the bizarre character of some of the views ascribed to him and also (as in the case of Aristotle) because his real interests were assumed to lie elsewhere. But neither of these lines of thinking can withstand scrutiny.

Fragment 29 gives earth and water as his dualist response to the ’basic substance’ question raised by the Milesians. Fragments 27-33 and testimonia A1, 32, 33 and 36-48 all address standard Ionian scientific topics. Fragment 18 asserts in part that ’as mortals search they discover (a) better’, and A33 (from Hippolytus) reports that Xenophanes based his theory of periodic flooding on the discovery of fossilized sea creatures at inland locations. The view of all atmospheric and celestial phenomena as essentially ’cloud’ (see A38-41 and 43-6) fits nicely with the description of ’great sea’ in fragment 30 as the source of all winds, clouds and waters, together with the view of fragment 27 that ’all things come from and return to (the) earth’. The breadth of Xenophanes’ scientific interests, his evident appreciation of the value of inquiry and observation, and the internal coherence of his explanations make it unlikely that he pursued scientific inquiry merely to acquire a weapon to wield against popular religion.

To charge Xenophanes with a belief in the earth’s ’infinite’ depth (fr. 28), ’infinite’ worlds (A1), and the sun’s ’infinite’ travels (A 41a) we would have to translate *apeiron* by ’infinite’ rather than the more plausible

’indefinite’. His eccentric view that the sun cannot shine without someone present to observe it (A41a) has been plausibly reinterpreted as the argument that since the sun is generated from rising moist vapours it cannot continue to exist in arid (hence unpopulated) regions. While Xenophanes’ scientific understanding was deficient in a number of respects, he remains a central figure in the Ionian scientific revolution.

5 Theory of knowledge

Xenophanes’ brief remarks about human knowledge were the subject of competing interpretations as early as the fourth century BC. Although sometimes regarded as an early statement of philosophical scepticism, they are best understood in the light of a traditional poetic contrast between the narrow scope of human experience and the synoptic view enjoyed by the gods (Homer, *Iliad* II 484-7; Semonides, fr. 1; Archilochus, fr. 70). Fragment 37 speaks in this vein when it links what mortals think to what they have experienced: ’If god had not made yellow honey, they would think that figs were much sweeter’. Fragment 36, ’… however many they have made evident for mortals to look upon’, suggests that what we can experience is neither unlimited nor entirely within our control. Fragment 35, ’let these be accepted, of course, as like the realities, but… ’, presents a similarly divided outlook: one should accept these (perhaps what Xenophanes presents as his account of the nature of all things) as true, but… (that is, certain knowledge exceeds our grasp).

In fragment 34 Xenophanes denies that anyone has known or ever will know ’the clear and certain truth (*to saphes*) about the gods and what I say about all things’, adding (in yet another ‘thought experiment’) that ’even if one were to say precisely what is brought to pass, he himself would still not know’. Since other ancient writers linked the possession of knowledge of *to saphes* with direct observation (Herodotus, II 44; Thucydides, I 22.4; Alcmaeon, fr. 1), Xenophanes’ argument can be analysed as a combination of a common view of the requirements for knowledge with the recognition that no account of the nature of the divine or the forces controlling the cosmos (including his own novel proposals on both topics) could possibly be confirmed on the basis of direct observation.

Xenophon (*c.*427-355/50 BC)

The Greek historian and philosophical writer Xenophon was a companion of Socrates, and is second in importance only to Plato as a source for our knowledge of him. He was also a penetrating and influential political thinker in his own right. He left Athens to embark on a spectacular military career in 401 BC, two years before Socrates' execution, and his military experiences had a deep impact on his thought and writings. An important historian and an innovator in literary forms, Xenophon limited his philosophical interests to political and ethical themes. Two questions are especially prominent: (1) What are the psychological roots of human virtue, and how can it be taught? (2) What are the limits of and the prospects for human attainment of self-sufficiency? He develops these themes most fully in two major works that present two competing models of the best human being. His Memoirs (usually referred to by the Latin title Memorabilia) presents the model of the philosophical life, mainly by recounting conversations between Socrates and a wide variety of human types. His The Education of Cyrus (often referred to by its Latin title Cyropaedia) presents the model of the political life, mainly by giving a fictionalized account of the rise to power of Cyrus the Great, founder of the Persian empire. Generally speaking, Xenophon seems in these works less willing than Plato and Aristotle to privilege the claims of philosophy over the claims of politics, and less optimistic about the power of reason to produce happiness. His works were highly esteemed by the Romans, as well as by such moral thinkers as Machiavelli, Montaigne and Rousseau.

1 Life

Born in Athens, Xenophon was in his youth a companion of Socrates. While still a young man he became an accomplished military leader, then in later life a distinguished prose author. He wrote two major historical works. The *Hellenica* covers political and military events from the late 400s down to the 360s. The autobiographical *Anabasis* is a pseudonymous account of his own greatest military success. It tells the story of how, although Socrates warned him of trouble ahead, Xenophon left Athens in 401 to join a Greek mercenary force hired by Cyrus, the younger brother of the king of Persia, for a campaign to take over the throne. (This Cyrus must not be confused with Cyrus the Great, founder of the Persian empire.) When Cyrus and the Greek generals were defeated and killed, the still youthful and inexperienced Xenophon was elected to take over leadership of the desperate Greek remnant, trapped in the middle of Asia Minor. He proved a brilliant commander, and saved the mercenaries by leading them to the Black Sea, where they met up with a Spartan force. His account of this expedition shows him a great tactician and skilful rhetorician. For obscure reasons, perhaps involving his Spartan connections, Xenophon was banished from Athens in the 390s, and subsequently served with distinction under the Spartan king Agesilaus. He did not return to Athens until the banishment was lifted shortly before his death in the later 350s.

Xenophon's thought and writings were deeply influenced by his military experiences. He was also a devotee of the vigorous outdoor entertainments of Greek gentlemen, and wrote influential practical treatises on hunting and horsemanship. Perhaps because of these influences and interests, scholarly opinion in the twentieth century tended to cast him as rather conventional and simple, lacking in the gifts of intellect and imagination necessary for original philosophical thought, or for a real appreciation of Socrates. But Xenophon was clearly a very brilliant and charismatic young man, in talents if not in tastes a rival of Alcibiades, to judge from their achievements. His moral wisdom was esteemed by the Romans (Cicero recommended Xenophon to his brother as the best writer on effective political leadership), as well as by moral thinkers such as Montaigne and Rousseau, who shared his lack of interest in more theoretical areas of philosophy. His intellectual interests and achievements are perhaps best compared to those of Machiavelli, who made much use of Xenophon. Both excel at thoughtful observation rather than theory construction, and both are model writers of clear, vivid and discreet prose, which often leaves their readers to draw out the lessons left implicit in their presentations of conversations and events.

2 Philosophical writings

After Socrates' execution in 399 BC, a number of his companions began to write reflections and remembrances about him, usually in the form of dialogues, and the style and approach of these 'Socratic discourses' defined them as a literary genre (see Socrates §§1-2, 7; Socratic dialogues). The genre came to include works in the dialogue style with protagonists other than Socrates, such as Cyrus the Great. Plato was of course far the greatest of the writers in this genre, but Xenophon was an honourable second. This is the literary context within which Xenophon

wrote his most directly philosophical works.

Many scholars in the nineteenth and twentieth centuries have tried to locate the true, historical Socrates by comparing and contrasting the Socratic dialogues of Plato and Xenophon. This search has reached no certain results. Some scholars have claimed that because Xenophon was a historian he is likely to be a better witness than Plato; others declare that because Plato was a ’real’ philosopher he could appreciate Socrates with a depth allegedly unavailable to the soldierly Xenophon. Neither position takes into account the peculiar nature of the genre of ’Socratic discourses’, best summarized by Arnaldo Momigliano: ’[B]iography acquired a new meaning when the Socratics moved to that zone between truth and fiction which is so bewildering to the professional historian. We shall not understand what biography was in the fourth century if we do not recognize that it came to occupy an ambiguous position between fact and the imagination…. With a man like Plato, and even with a smaller but by no means simpler man like Xenophon, this is a consciously chosen ambiguity’ (1993: 46).

Xenophon constructed his Socratic writings with a view to thinking about the moral and political issues raised by Socrates’ way of life. He emphasizes primarily what furthers his own thinking, not what gives a full or historical portrait of Socrates. Where he differs from Plato, the difference is more likely to reflect their different estimates of Socrates’ significance than their different recollections of the historical Socrates. Both bend historical fact to the service of moral analysis.

Xenophon wrote six works in this genre of Socratic discourses. His *Apology of Socrates to the Jury* and *Symposium* appear to be responses to Plato’s works of the same titles. The *Oeconomicus* is in part a response to the comic attack on Socrates in Aristophanes’ *Clouds*. The *Hiero* is a conversation about political power between Hiero the tyrant and Simonides the poet. His two major philosophical works, the *Memorabilia* and *Cyropaedia*, focus on two philosophical issues: (1) What are the psychological roots of human virtue, and how can it be taught? (2) What are the limits of and the prospects for human attainment of self-sufficiency? Generally speaking, Xenophon seems in these works less willing than Plato and Aristotle to privilege the claims of philosophy over the claims of politics, and less optimistic about the power of reason to produce happiness.

3 Virtue and education

Xenophon presents both Socrates and Cyrus the Great as educators, and has much to say about their influence on others. His Socrates is presented in the *Memorabilia* primarily through the educational effect he has on his companions, while the *Cyropaedia* is as much about the education that Cyrus *gives* to those he commands as it is about the education he *receives* in his youth. In these works, Xenophon presents no general theory or scheme of education comparable to, for example, Plato’s in the *Republic* (see Plato §14). Instead, he emphasizes the many ways in which moral formation must accommodate the particular aspirations and even prejudices and vices of those to be educated. Through the contrast between Socrates and Cyrus as educators, Xenophon reveals a stark choice between two competing possibilities for human virtue (see Aretē), but without clearly privileging one possibility over the other. He seems more interested in exploring the ambiguities of virtue than in making a case for one type over the other.

Xenophon’s Socrates influences others partly through precepts he teaches in conversation, partly simply through the force of his own example. The moral advice and example he imparts amount to commentary on the two great maxims inscribed over the portico of the oracle of Apollo at Delphi: ’Know thyself’ and ’Nothing in excess’. In conversation, Xenophon’s Socrates is a master of refutation (elenchus), like Plato’s Socrates (see Socrates §§3-4). These conversations often demonstrate to Socrates’ interlocutors that they are ignorant of what they must know to live up to their own aspirations. But Xenophon’s Socrates is more willing than Plato’s to offer explicit moral advice, at least to receptive young men whose pride has been humbled by refutation, and quicker to drop the pose of being a mere questioner who has no knowledge of his own. He teaches his companions to consider how much knowledge they must really have to prosecute successfully the projects they want to undertake, especially when these projects involve political power. The knowledge required turns out in part to be quite practical, such as how to guarantee Athens’ grain supply or the productivity of the silver mines. But it also requires answers to more philosophical questions, such as whether a young man will benefit from wielding great power rather than being destroyed by it. Xenophon has his Socrates show how ambition often would be made less rash if forced to acknowledge such considerations. In addition, Socrates exhorts his companions and inspires them through his own example to an ascetic control over passion and desire. He presents his own ascetic way of life as the foundation of

his freedom, and Xenophon makes this freedom the heart of people's fascination with Socrates. Indeed, Xenophon's portrait seems to give Socrates' freedom precedence over his wisdom, probably in conscious competition with Plato's portrait.

Xenophon's Cyrus is also a paragon of knowledge and self-control, but his example and his exhortations have an essentially different emphasis from those of Xenophon's Socrates. In general, Socrates improved the virtue of his companions by deflating their ambitions and reining in their desires. Cyrus instead convinces his followers that virtue is an indispensable means if they are to reach the ends of glory and wealth that they seek. The crucial moment in Cyrus' rise to power, as Xenophon presents it, comes when he convinces his Persian troops to pursue virtue, not for its own sake, but for the rewards that come from it. For this sort of education in virtue to take hold, it is absolutely necessary that the 'students' have vigorous desires for wealth and passions for power; such a psychological endowment is the fertile ground out of which Cyrus grows virtue, whether his own or other people's. Xenophon shows that this view of virtue creates a difficult dilemma for the leader: the very desires and passions that make talented people virtuous and therefore manageable by the effective leader also motivate them to become rivals for power. Cyrus is a master at using others' talents without undermining his own position of authority. The importance of this theme in the *Cyropaedia* explains why Xenophon's Cyrus is such an important point of reference in Machiavelli's *Prince* (see Machiavelli, N.).

This tension between Socrates and Cyrus as moral educators reveals an ambiguity about the nature and preconditions of virtue that is also prominent in two of Xenophon's smaller contributions to the genre of 'Socratic discourses'. His *Oeconomicus* shows Socrates trying to convince the young and rather irresponsible Critobulus to take more care of his family's wealth. This treatise on the household was a popular classic with the Romans, but it might seem odd that it should also be a vehicle for exploring political themes about virtue. In the conversation with Critobulus Socrates makes explicit the connection between the themes: he claims that there is in principle no difference between governing a city and governing a household, a claim also found in Plato's *Statesman* (see Plato §16). Most of the dialogue is taken up with Socrates' account of the teaching about household management of a gentleman farmer named Ischomachus. A critical component of household management as Ischomachus understands it is knowing how to motivate one's wife, servants and slaves to promote one's own good. In effect, Ischomachus looks for the same psychological endowment in these domestic subordinates that Cyrus sought in good soldiers: strong desire mixed with prudent calculation. Xenophon presents a politically more provocative version of essentially this same view of leadership and moral education in his *Hiero*, a dialogue between Hiero the tyrant and Simonides the poet about the costs and benefits of tyranny. Hiero complains that the best men in his city are exactly the ones most irked by subjection to his rule, and especially by the presence of his personal bodyguard of mercenaries. Simonides suggests that the tyrant can make himself more acceptable to these best men if he deploys the mercenaries to aid his subjects in controlling their own slaves. In other words, appeal not just to their desire for wealth or glory, but directly to their own interests in despotism. This will make the mercenary bodyguard palatable to the best men, even although it is the guarantee of their own subjection.

4 Self-sufficiency and the divine

Xenophon also considers Socrates and Cyrus in themselves rather than in their influence on others. This allows him to compare the highest achievement possible within the ways of life of philosophy and politics. For Xenophon, this comparison focuses on the extent to which the two ways of life achieve self-sufficiency (*autarkeia*). He conceives of self-sufficiency as a defining attribute of the divine, so that it is no mere figure of speech to say that Xenophon's two heroes represent two different paths to apotheosis. Here again, Xenophon is engaged in an examination that also engaged Plato and Aristotle, as well as the tragedians and Herodotus. And here too Xenophon refuses simply to subject the aspirations of the political life to a philosophical critique. Instead, he brings out the limitations of *either* political power *or* philosophy for living up to the aspiration to self-sufficiency. To a large extent, Xenophon opposes the position of Aristotle (§26), who said that humans should not merely think human thoughts, but should try to be as divine as possible.

Xenophon's Socrates seems to believe that both paths to divinization, the philosophical and the political, are impious and based on a failure to acknowledge divine constraints on human ambition. He rejects outright the claims of natural philosophers that the study of the cosmos is humanity's highest accomplishment. He denies that

they in fact have the knowledge of divine things they claim, and defends the Delphic view that 'Know thyself' takes precedence over any other investigation. To political ambition his response is more complicated. He fascinates his politically ambitious young companions because they see in him an image of the self-sufficient control over happiness to which they aspire. They are not sure how he does it, but they think that spending time with him will surely let them in on the secret. Socrates lets them believe this, and the tempting and teasing that result are at the core of Socrates' claim that his life is filled with *erōs* (love). Ambitious young men conceive an erotic passion for Socrates because they see him as the means to the knowledge, especially the self-knowledge, required by their political projects. Xenophon exposes the vanity of this passion by showing that, while in a sense Socrates does have the divinizing wisdom such men seek, it cannot be communicated or exchanged. Socrates' secure possession of the knowledge of what makes humans happy is ultimately supernatural: his wisdom is grounded in his 'divine sign', which is his unique prophetic endowment. This 'divine sign', a voice that occasionally gave Socrates advice and which is also reported by Plato, is crucial to Xenophon's understanding of how Socrates chastened the political ambitions of his companions. Socrates forced them to acknowledge that their own lack of this supernatural wisdom was an insuperable limitation to their pursuit of self-sufficient control over their own political success.

On this issue, too, Cyrus is the vehicle Xenophon employs to explore a less uncompromising view of the potentialities of the political life. His Cyrus does not have Socrates' sure access to divine guidance about which choices will prove beneficial or harmful. But he has the best 'political' approximation to the 'supernatural' divine sign of Socrates: he knows how to be his own diviner, so that he will never be at the mercy of anyone else's interpretation of sacrifices, omens or other signs of the divine purpose. Besides the useful information this pious dependence on divination provides to Cyrus, it is also a powerful rhetorical tool, for people are happy to follow a leader who seems to operate with divine favour. (The *Anabasis* shows that Xenophon was fond of such rhetoric himself.) Cyrus can then achieve a sort of self-sufficient control within politics that avoids the demands of knowledge that Socrates impressed upon his interlocutors. Thus Cyrus shows the farthest extreme of merely human control over success, a control whose limitations are brought into focus by comparison to Socrates.

Xin (heart-and-mind)

In the West, questions of the distinguishability of mind and matter and of rationality and emotion or sentiment are central issues within the philosophy of mind. Neither of these topics is of much interest, however, to the mainstream of Chinese thought. On the one hand, the notion of qi*, the vital energizing field that constitutes all natural processes, renders discussions of the relevance of any psychophysical dualism moot. On the other hand,* xin*, normally translated as 'heart-and-mind', preludes the assumption of distinctions between thinking and feeling, or idea and affect.* Xin *is often translated simply as 'heart', but since it is the seat of thinking and judgment, the notion of mind must be included in its characterization if the term is to be properly understood. Indeed, what we often think of as 'will' or 'intention' is likewise included in the notion of* xin*.*

In the classical period, the heart (*xin*) as the seat of thinking is considered to be an organ similar to the other sensing organs, but with the advantage of being able to think: 'Organs such as those of hearing and of sight, being unable to think, can be misled by external things.… But the heart does think. Only by thinking will the answer be found' (*Mengzi* 6A15). Such a characterization is not, of course, unique to the Chinese; the classical Hebrews also believed the heart to be a seat of thought and action.

The interpenetration of idea, intention and affect expressed in the notion of *xin* entails the conclusion that thinking is never a dispassionate speculative enterprise but involves normative judgments which assess the relative merit of the sensations, inclinations and appetites that interpenetrate our experience of the world and ourselves. Since appetites and ideas are always clothed with emotion, they are to be understood, more often than not, as dispositions to act. (We have here some basis for understanding what is often thought to be the paternalistic desire of Chinese governments, from the classical period to the present, to protect the people from the 'disruptive' consequences of ideas.)

Another implication of the unity of feeling and thinking is the practical orientation of most of Chinese thought. If ideas are dispositions to act, what might be thought of as theories are little more than wholesale practical recommendations. Thus it is most difficult in Chinese cultures to find contexts within which the separation of theoretical and practical activities would prevail. When, for example, Confucius said, 'at fifteen my heart-and-mind was set upon learning' (*Analects* 2.4), he was indicating his commitment to an ethical regimen aimed at self-realization. Thinking and learning are, within the Chinese tradition, oriented to the practical ends of the moral life (see Self-cultivation in Chinese philosophy). As Mencius observes: 'For a person to realize fully one's heart-and-mind is to realize fully one's nature and character' (*Mencius* 7A1).

Western people are accustomed to think of efforts aimed at moral perfection (see Perfectionism) as involving a struggle between reason and passion, or between what we believe we ought to do and an obstreperous will that frustrates the enactment of that belief, or in the words of St Paul: 'The good that I would do I do not do, and the evil that I would not do, that I do.' In the Chinese tradition there is little such internal conflict involved in ethical development. The unpartitioned self characterized by *xin* means that it is unlikely that we should find Hamlets or St Pauls prominent among the Chinese.

If, however, the conflict associated with self-realization is not between heart and mind, what are the dynamics of moral development? If the problematic of unrealized selfhood does not entail the self divided against itself, what is the source and nature of the disturbance that the moral discipline is meant to overcome? If it is not located primarily within the soul, it can only be a disturbance in the relationships which constitute the self in its interactions with external things. 'The stillness of the sage is not a matter of his saying: "It is good to be still!" and thus he is still. He is still because none of the myriad things are able to agitate his heart and mind' (*Zhuangzi* 13).

It is precisely *not* through an internal struggle of reason against the passions, but through mirroring the things of the world as they are in their relatedness to us, that we reach a state in which 'none of the myriad things is able to agitate' our hearts-and-minds. In other words, we defer to the integrity of those things which contextualize us, thus establishing a frictionless relationship with them.

Xin (trustworthiness)

The earliest and basic sense of xin *is 'being true to one's word'. While one's words can be* xin *(that is, worthy of trust), in most cases* xin *indicates an excellence of character; it is thought to be the central virtue governing the relationship between friends. Since* xin *is primarily a virtue, its exercise involves practical reasoning and not a mechanical adherence to one's promises.* Xin *later was added to an original list of four cardinal Confucian virtues, though its status as a distinct disposition remained controversial. Buddhist thinkers broadened the sense of the term to include religious faith. This innovation in turn influenced certain neo-Confucian thinkers who then talked about the need to* xin *(have faith in) one's innate moral faculty.*

The basic sense of being trustworthy and reliable is well-attested in some of the earliest appearances of the character *xin*. In the *Zuozhuan* (Zuo Annals), a true and reliable worshipper is described as *xin* (Duke Zhuang, 10th year), as is a son who can be counted on to uphold and maintain his father's orders (Duke Xi, 7th year). In both cases, *xin* is used to describe someone who can be trusted to fulfil and not overstep their proper religious and ethical obligations.

In a variety of early texts, *xin* is linked with another character to form the pair *zhong xin* (loyalty and trustworthiness). These two virtues are seen as cognates: those who are *zhong* (loyal) steadfastly maintain their obligations, which makes them *xin* (trustworthy). Again, however, they are not 'loyal' and 'trustworthy' in a blind or mechanistic fashion. Their allegiance is to the moral way.

During the Han dynasty, *xin* was added to the four cardinal virtues of humanity, righteousness, propriety and wisdom (see Zhi; Confucian philosophy, Chinese §§5-6) first put forth by Mencius (*Mengzi* 2A6). This addition posed a problem for later Confucian philosophers, as the virtue *xin*, unlike the other four, was not associated with a corresponding nascent tendency of the human heart-mind. Cheng Yi accounted for this asymmetry by regarding *xin* as a kind of meta-virtue which supervenes upon and emerges from the original four. Zhu Xi believed that it was the ground or necessary constituent of the other virtues.

Xin was used as a verb to mean 'to believe or trust' (for example, in the *Daodejing* 49) and hence could mean faith in the sense of mental assent. However, since indigenous Chinese religion and ethics were strongly naturalistic, there was little room for a notion of 'faith' in the sense of *fiducia*. However, with the arrival of Buddhism (see Buddhist philosophy, Chinese), it came to mean 'belief' or 'faith'; in this latter, voluntaristic sense, in a teaching, text, order or deity. This is clearly its meaning in the title of Buddhist works such as the *Dasheng qixinlun (The Awakening of Faith in Mahāyāna)* (see Awakening of Faith in Mahāyāna).

This sense of *xin* as the attitude or spiritual virtue which provides one with the motivation to remain true to what is right and good is seen in later Confucian thinkers such as Wang Yangming. Wang believed that all people are endowed with a complete and perfect moral faculty called *liangzhi* (pure knowing) which, given full rein, had the power to eliminate all misguided tendencies and steer one unerringly to what is right and good. The challenge was to generate a full and active commitment to follow one's *liangzhi*, a task which Wang once described as 'creating something out of nothing'. His advice to simply *xin* (have faith in) *liangzhi* is similar to the kind of religious faith familiar in Christian thinkers such as Luther.

Xing

Xing *is conventionally translated as ‘nature’ or ‘human nature’. Some read* xing *as meaning a heavenly endowed tendency, directionality, or potentiality of growth in the individual. On this essentialistic reading,* xing *is an innate and unchanging ‘given’, a defining condition of all human beings. Others have given a historicist interpretation of* xing*, reading it as an achievement concept rather than as a given. In this view,* xing *is derived from, and is a refinement on,* sheng*, denoting the entire process of birth, growth and ultimate demise that constitutes the life of a living creature.*

There is some controversy in the published literature on the meaning of *xing*, conventionally translated as ‘nature’, or ‘human nature’. On one side, there are those who read *xing* as a heavenly endowed tendency, directionality, or potentiality of growth in the individual, and see it as similar to the Greek *phuo* (to grow) and the Latin *nascor* (to be born) (see Human Nature; Essentialism). On the other side, there are those who have an historicist interpretation of *xing*, reading it as an achievement concept rather than as a given. A.C. Graham (1990) takes issue with the simple identification of the classical Chinese concept of *xing* with the familiar conception of ‘nature’ as something ‘inborn and innate’, those qualities which a thing has to start with. His claim is that the dynamic thrust of *xing* has not been adequately noticed.

As a corrective on his own earlier work, Graham argues that early Chinese thinkers who discuss *xing* seldom seem to be thinking of fixed qualities going back to a thing’s origin, but rather to the process of its maturation within a specific context. *Xing* thus understood covers the career of a person’s existence, denoting the entire process of becoming human. Strictly speaking, a person is not a sort of *being* but first and foremost a *doing* or *making* and, only derivatively and retrospectively, something done.

If we were going to speculate on why terms such as *xing* tend generally to be more dynamic in meaning than their Western equivalents (which indeed seems to be the case), we might want to reflect on the implications of cosmogonic speculation, a signal feature of the Western tradition that is made important in this analysis by its absence in classical Chinese cosmology. Where something within a single-ordered *kosmos* is shaped and invested by an external originative principle, the most fully creative act lies in the creator’s endowment of a given potential: the creature’s subsequent actualization of that potential is derivative. Where a phenomenon is initiated by, and dependent upon, some externally derived or ‘given’ creative principle for the ‘nature’ of its existence and, put another way, where it is other than self-generative (*ziran*), the creative contribution of that phenomenon tends to be diminished. In the absence of cosmogonic beginning, on the other hand, the power of creativity and the responsibility for creative product reside more broadly in the phenomena themselves in their ongoing interactive processes of becoming (see Tian; Dao).

The difference between the ‘nature’ of a thing in a cosmogonic tradition and its *xing* in a non-cosmogonic cosmology is suggested by the kinds of questions that each culture’s philosophers ask. Cosmogonic concern generates metaphysical questions, a search for essential principles. How did the cosmos begin? What are its first principles? What are the fundamental elements from out of which it was constructed? What is the origin of the existence and growth of natural phenomena? The search is for the One behind the many.

Genealogical cosmology, on the other hand, will generate primarily historical and rhetorical questions: who and what are our historical antecedents that have given us our present definition? What are their achievements that we can appropriate to enculturate ourselves? How can we further cultivate ourselves so as to contribute to the appropriated tradition as it is embodied in our contemporary exemplars? How can we turn this historical and cultural interdependence to maximum benefit? The thinker’s role in the non-cosmogonic tradition, then, will not be as much to discover an answer as to create a model of humanity that is persuasive, and that evokes emulation.

A related implication of this distinction between a cosmogonic and non-cosmogonic worldview is that in the absence of some overarching *archē* (beginning) as an explanation of the creative process, and under conditions which are thus ‘anarchic’ in the philosophic sense of this term (see Archē), although *xing* might indeed refer to ‘kinds’, genus and species as categories would be dependent upon generalizations made by analogy among *sui generis* phenomena. Difference is prior to identified similarities. Certain things to which *xing* is applied - water

and rocks, for example - are not over their respective careers marked by growth and cultivation, and hence it makes little sense to speak of them in terms of starting conditions and mature state. The *xing* of such things remains relatively constant. However, the human being - that phenomenon most given to cultivation and refinement - is a different case.

While the human *xing* might include certain generalizable conditions that define it at birth, in its more important aspects it seems to refer to what is existentially achieved. In defining the human *xing*, the relatively constant and uninteresting tendencies which constrain the creative project of personal development are outweighed by the massive transformative process that occurs between the ‘stirring’ or ‘germination’ of the initial fundament and the full-blown creative achievement. What is ‘innate’ in the *xing* of persons is simply the propensity for growth, cultivation and refinement. *Xing*, then, denotes a human capacity for radical changeability that is qualitatively productive.

Further, *xing* is realized *in situ*. It is a dynamic process conditioned by its particular context. Stated more explicitly, the human *xing* is a creative process that can only be understood situationally as the outcome of specific interdependent relationships. It at once refers to the continuing existence of a particular thing itself, and also to that in one thing which continues the life and culture of other things.

Xunzi (*fl.* 298-238 BC)

Xunzi is one of the most brilliant Confucian thinkers of ancient China. His works display wide-ranging interest in such topics as the relation between morality and human nature, the ideal of the good human life, the nature of ethical discourse and argumentation, the ethical uses of history, moral education and personal cultivation. Because of the comprehensive and systematic character of his philosophical concerns, Xunzi is sometimes compared to Aristotle. Noteworthy is his emphasis on li, *or rules of proper conduct, and the holistic character of* dao, *the Confucian ideal of the good human life. He criticized other philosophers not because of their mistakes, but because of their preoccupation with one aspect of dao to the exclusion of others.*

Xunzi (Hsün Tzu) is also known as Xun Kuang and Xun Qing. His fundamental doctrines are contained in the *Xunzi*. Like his predecessors, Confucius and Mencius, Xunzi focuses on developing a conception of a well-ordered society governed by an enlightened, virtuous and sagely ruler, a ruler who cares for people's welfare and moral character based on the cultivation of *ren* (benevolence), *li* (propriety) and *yi* (rightness, righteousness). The enlightened ruler is one who is good at organizing the people in society in accordance with *ren*, *li* and *yi*.

The *li*, as formal prescriptions or rules of proper conduct, are especially emphasized by Xunzi. While they represent an inherited ethical tradition, they do not always provide adequate guidance in the perplexing, exigent situations of human life. As markers of *dao* (the Way), 'the *li* provide models, but no explanations' (*Xunzi* 1, in Watson 1963: 20); basically they provide general guidelines delimiting the boundary of proper behaviour and individual responsibility. Perhaps even more important, the *li* 'provide for satisfaction of people's pursuit' of their individual desires or interest (*Xunzi* 19). In this respect, the *li* may be compared to the laws of contracts or of wills, enabling the agents to fulfil their desires effectively. Of course the key question, whether the existing *li* in fact perform their proper functions, depends on whether they satisfy the requirements of *yi* (that is, whether they are the right sort of rules) and the extent to which they ennoble human character in terms of *ren* (benevolence) and cultural refinement (*wen*) (Cua 1989) (see Confucian philosophy, Chinese).

For Xunzi, the regulative or delimiting function of *li* is important in ensuring a good, stable social and political order. The necessity of the *li* is due to the problematic motivational structure of human nature. This is the force of his rather misleading remark that 'the human's nature is evil; his goodness is the product of conscious activity' (*Xunzi* 23, in Watson 1963: 157). In terms of its inborn motivational structure, consisting of feelings and desires, every human is a self-seeking animal actuated by fondness for personal gain. In the absence of regulative rules, this propensity may be viewed as bad or evil because it tends to lead to conflict and disorder in society. What is good is that which is 'upright, reasonable and orderly' and what is bad is 'that which is partial, irresponsible and chaotic' (*Xunzi* 23, in Watson 1963: 162). In addition, scarcity of resources to satisfy everyone's desires will lead to competition which requires *li*-regulation as well as a sense of *yi* (rightness).

In this light, inborn human nature is value-neutral, not intrinsically bad or evil but requiring regulation and moulding. This nature provides the basic materials for ethical transformation as does clay for the making of pottery. Indeed, in respect to human nature, the sage and ordinary humans are alike. Every man can become a sage: 'What makes the sage emperor Yu a Yu was the fact that he practised *ren* and *yi* and complied with proper rules and standards of conduct.' Moreover, the rationales of *ren*, *yi* and proper rules and standards can be known and practised by ordinary persons, because they possess the capability of obtaining such knowledge and acting accordingly. It must be admitted that not every person can actually become a sage, for they are not willing to make the effort, especially in moral learning (*Xunzi* 23).

Xunzi's essay 'Encouraging Learning' presents a sketch of his conception of moral learning as a continuing process that ceases only with death. Principally, the learning is devoted to acquiring knowledge of various classics such as the *Shijing (Book of Songs)*, the *Shujing (Book of Documents)*, the *Lijing (Classic of Rites)* and the *Spring and Autumn Annals*, as well as the established musical text. While recitation is stressed, Xunzi calls attention to understanding and insight concerning the concrete significance of these works in human life. Initially, learning to be an ethical person depends on teachers of exemplary ethical character, but this learning continues throughout one's life. The proximate objective is to become a scholar-official; the ultimate objective is to become a sage. Notably, the classics provide an introduction to what Xunzi considers as the best Ru or Confucian tradition.

Xunzi's own writings attest to the importance of acquiring historical knowledge (Cua 1985b). Special stress is given to four different functions of the ethical uses of history in discourse: pedagogical, rhetorical, elucidative and justificatory uses (see History, philosophy of).

These uses of history provide a better guidance than religious beliefs and superstition about *tian* (Heaven) as dispensing fortunes and misfortunes (see Tian). *Tian* is a natural order of regularities, not an order governed by a supreme, personal being. The proper attitude toward strange events or phenomena is wonder and awe (*Xunzi* 17). Practices such as prayer and divination are based on superstitious beliefs. However, the *li* or rites of mourning and sacrifices are ethically acceptable and, in fact, to be encouraged. Their significance lies in their function of satisfying human yearnings and providing an avenue for the proper expression of reverence, honour and affection for the dead. Moreover, these rites contribute to the Confucian conception of cultural refinement (*wen*) (*Xunzi* 19). Moral learning culminates in the attainment of completeness and purity, that is, a state of ethical integrity (*Xunzi* I) (see Moral development).

Xunzi frequently uses the word *dao* to express his ideal of the good human life as a whole. The significance of *dao* as a generic term lies in a practical understanding of *ren*, *li* and *yi*. However, knowing *dao* requires clarity of mind (*ming*). When a clear mind is guided by reason, it will be free from all sorts of factors that obscure (*bi*) the clarity of vision. One must be especially watchful of the contextual significance of such distinctions as between desires and aversions, immediate and distant consequences, the past and the present. Failure to weigh the relevance of one item of the distinction is liable to blind the agent to consideration of the significance of the other item. Basically, distinctions are relative to the purpose and context of discourse; they are not exclusive disjunctions or absolute dichotomies. Since distinctions in general are the products of the mind's intellectual function at the service of cognition and action, their utility in a particular situation is also relative to purpose and context. Even in cases where the utility of the distinction is not in question, the agent must render a reasoned judgement concerning the significance of each item in the distinction. Obscuration (*bi*) of the mind arises when the mind exclusively attends to the significance of one item without proper regard for that of the other (see Perception, epistemic issues in).

Even philosophers are susceptible to *bi*. Mozi, for example, exaggerates the importance of utility without understanding the importance of culture or the beauty of forms; Zhuangzi is preoccupied with *tian* (Heaven) without regard for humanity. In general, ordinary people as well as philosophers tend to see only 'one corner' of *dao* and thus fail to appreciate its holistic character. Only an enlightened sage 'confronts all things and weighs them impartially on a balance' (*Xunzi* 21; Cua 1993).

Today, Xunzi is widely acknowledged to be one of the greatest Chinese philosophers. Apart from his critical and coherent exposition of ancient Confucianism, he is also distinguished for his insights into the nature of ethical knowledge and argumentation (Cua 1985a).

Yang Xiong (53 BC-AD 18)

Master Yang Xiong, the first Confucian classicist and the greatest of the pre-Song metaphysicians, is best known for two major philosophical works, the Taixuanjing (Canon of Supreme Mystery) and the Fayan (Model Sayings). Both works explore the interaction between significant cosmic and social patterns by explicit reference to earlier canonical traditions.

Master Yang came to Changan (modern Xian), then the capital of the Western Han dynasty, in his early thirties. As the foremost poet of his age, Yang Xiong was in effect appointed poet laureate to the court in 10 BC. In middle age, after the death of his beloved son, Yang experienced a sense of profound revulsion for his earlier poetic efforts. Condemning court poetry as inherently frivolous, if not immoral, Yang turned to composing works of philosophy.

His first such work was the *Taixuanjing (Canon of Supreme Mystery)*, which like its prototype, the *Yijing (Book of Changes)*, correlates the significant patterns of the universe with different combinations of solid and broken lines accompanied by brief texts and ten autocommentaries. However, the *Taixuanjing* adjusts the structure and imagery of the *Yijing* to better address Han preoccupations with correlative thinking, fate and time. As the first grand synthesis of Chinese thought, skilfully weaving together elements of early Confucianism, classical Daoism, *yin-yang* Five Phases theory (see Yin-yang), alchemy, and astrology into an organic whole, the *Taixuanjing* came to occupy a place in Chinese intellectual history roughly comparable to that of the *Summa theologiae* of Thomas Aquinas in the West. Its most important contribution is its account of individual human destiny, which is said to result from the interplay of four major factors: time (meaning 'present opportunity'), virtue (or 'character'), tools (including training) and position (societal and physical). Of these four factors, only virtue is completely subject to human control, so Yang identifies adherence to the Good as defined in the Confucian 'Way' as the single most reliable method of improving individual fate. In the course of outlining this theory of fate, the *Taixuanjing* pinpoints the logical fallacies inherent in various philosophical positions that competed with Confucianism for general approval during Yang's time.

Following a draft of the *Taixuanjing* before 2 BC, there came at least four lengthy philosophical poems whose style parodies the prose-poems of Yang's youth. Two of these *fu* are dedicated to the defence of his provocative masterwork, the *Taixuanjing*. Around AD 12, Yang finished the *Fayan (Model Sayings)*, which adopts both the format and style of the Confucian *Analects* to provide a relatively straightforward catechism for the would-be sage (see Confucius). The *Fayan* evaluates the conflicting goals of immortality, fame, power and scholarship to disentangle prevailing notions that confused the 'good life' with ideas of the Good. As its main theme is the need to immerse oneself in the model of the former sages, the *Fayan*, like the *Analects*, devotes considerable attention to the reassessment of historical figures whose conduct or writings were considered worthy of emulation (see History, Chinese theories of).

When Yang died, he left unfinished a third remarkable work on significant pattern, the *Fangyan (Regional Expressions)*. As the first Chinese dialect dictionary, the *Fangyan* is far more than a sourcebook of philological glosses culled from disparate sources; it is a synchronical word list that focuses on rare expressions in an attempt to trace linguistic boundaries and connections. In a surviving letter, Yang justified the enormous task of compiling this text in fairly standard Confucian terms: Since regional cultures evolve from complex factors, the wise ruler must have such texts at his disposal so that government policies may be suitably adjusted to varying locales.

Thanks to the volume and quality of his output, Yang's stature as Confucian master remained unchallenged until the Song period. At that time a few prominent neo-Confucian thinkers (including Zhu Xi), in an effort to disengage themselves from certain pre-Song moral constructs, objected to Yang's considerable influence and denounced his character, cosmological vision and eclecticism. Nonetheless, as most Chinese philosophical works dating to the first millennium have been lost, the *Taixuanjing* and *Fayan*, two undisputed classics, together provide one of the best keys to understanding early Confucian ideology in its formative stage.

Yangzhu (5th-4th century BC)

Yangzhu, detested by the Confucians, is important in the Chinese tradition for initiating the explicit discussion of human nature. He focuses on the thesis that human nature has no inherent ethical or mystical qualities; instead, there is simply an innate tendency to live a long life, a tendency that must be carefully nurtured by a rational regulation of sense stimulation and by the avoidance of any of the entanglements incumbent in a life of working for the good of human society.

Yangzhu is commonly dated to a generation or two before Mencius, who said of him that he was so egotistical he would not even pull out one hair to benefit human society. There are no extant writings of Yangzhu; we know of his ideas through the writings of his followers included in five essays in the *Lushi chunqiu (Lu's Spring and Autumn Annals)* in the third century BC, and in four chapters from the *Zhuangzi* that are dated to about 205 BC (see Lushi Chunqiu; Zhuangzi). There is no evidence of his intellectual lineage continuing after this time.

Yangzhu is known for initiating in Chinese thought the explicit discussion of human nature (see Xing), and also for three related teachings: 'keeping one's nature intact', 'protecting one's genuineness' and 'not letting the body be tied by external things'. For Yang, human nature at its most basic level consists in the spontaneous tendency for humans to live a long life if undisturbed by external things, since the various 'physiological' systems of *qi* that constitute the human organism tend to function harmoniously provided they are unimpaired and sufficiently nourished by the proper degree of sensory stimulation (see Qi).

A related aspect of human nature is the desire of the various sense faculties for their objects. It is this that helps to maintain the health and development of the organism, enabling it to realize its inherent tendency for longevity. However the senses, themselves, need to be regulated and limited to only a suitable amount of stimulation; there is a naturally suitable degree of sense-stimulation which is conducive to health and development. This degree must be rationally determined by the Sage; the senses on their own cannot do this. Excessive stimulation, say the Yangists, reduces the individual's finite supply of the refined form of *qi* called *jing* (vital essence) needed to maintain health and vitality.

Yangist political philosophy is meagre, but straightforward. One should not seek after fame, wealth and power, all of which are far beyond essential needs. One should never do anything to impair one's inherent tendency to live a long and satisfied life. Only when a person knows this do they understand 'the essentials of our nature and destiny' and are then fit to rule over others.

Yangzhu's challenge to the social interpretation of human nature of the Confucians consisted in the primacy he placed on the maintenance of the individual. In his advocacy of personal cultivation over social concern, he initiated an individualistic counteractive to the often overwhelming pressure toward social conformity in China that was later continued by Daoist and Buddhist thought. However unlike these later schools, there was absolutely nothing mystical in the teachings of Yang and his followers, even though some think them related to the early Daoists.

Yi Hwang (1501-70)

Yi Hwang, also known by his honorific name T'oegye, is one of the two most honoured thinkers of the Korean neo-Confucian tradition. His fully balanced and integral grasp of the complex philosophical neo-Confucian synthesis spun by Zhu Xi during China's Song dynasty marks the tradition's arrival at full maturity in Korea. His 'Four-Seven Debate' with Ki Taesûng established a distinctive problematic that strongly oriented Korean neo-Confucian thought towards exacting investigation of critical issues regarding the juncture of metaphysics and their all-important application in describing the inner life of the human heart-and-mind.

Yi Hwang, also known by his honorific name T'oegye, was born of a relatively modest aristocratic lineage in the village of Ongyeri, near Andong in Kyongsan province, about 200 kilometres southwest of Seoul. He took the civil service examinations, and served in government for a number of years, but his true longing was for a life of quiet study, reflection, and self-cultivation. He retired from office in his late forties to pursue his dream, and the following two decades were a period of tremendous productivity in spite of frequent recalls to office as his fame as a scholar and teacher grew.

Neo-Confucianism was adopted as the official orthodoxy at the foundation of the Chosôn dynasty in 1392. It was a rich synthesis, containing a metaphysical system of Daoist proportions and a meditative cultivation of consciousness reminiscent of Buddhist practice which Zhu Xi and other early neo-Confucians had woven about the core of traditional Confucian concerns for government and proper social ethics (see Neo-Confucian philosophy). It provided wide scope for varied and uneven development. During the first century of the Chosôn dynasty, activists in government focused on institutional reform while, far from the capital, scholars in the countryside concentrated on the more meditative features of neo-Confucian learning and self-cultivation. The differing orientations crystallized into bloody clashes and purges by the end of the fourteenth century as young men steeped in moral rigorism began to move from the countryside into government.

Yi Hwang's comprehensive grasp of Zhu Xi's thought clarified the balance between activity and quietism, government and retired self-cultivation, and by the end of his life it was his disciples who were moving into high government positions. A year before his death he crystallized and presented to the king his understanding of the way in which metaphysics and psychological structures inform ascetical theory and eventuate in the conduct of daily life. This work, the *Sônghak sipdo (Ten Diagrams on Sage Learning)*, became one of the most famous and influential works of Korean neo-Confucianism. After Yi Hwang, it was no longer possible to deny the legitimacy of intensive, almost monastic devotion to study and meditative self-cultivation when the situation permitted, nor to ignore the expectation that the proper fruition of such formation should be the proper conduct of government and the ordering of society.

On the level of philosophical theory, Yi Hwang left a lasting imprint on Korean neo-Confucianism, for his 'Four-Seven debate', carried on in correspondence with a younger scholar, Ki Taesûng (1527-72), established the problematic for Korean thinkers for centuries. In particular, it centred Korean neo-Confucian reflection on questions relating to the interface of metaphysics and psychological theory. For Yi Hwang and other neo-Confucians committed to self-cultivation, this was a topic of intense concern: in the framework of neo-Confucian thought, a proper, metaphysically-grounded understanding of the structure and functioning of the psyche explains human perfection and imperfection; it is thus the foundation for any theory behind the practice of spiritual cultivation.

The Four-Seven Debate centred on an issue directly related to one of the most important advances of neo-Confucian thought, its explanation of a cause within human beings that could disrupt our natural responsiveness to situations and cause us to err. This was accomplished by the elaboration of a dualistic monism. The single *dao* or *li* (in Korean, *to* and *i*), both formative and normative, runs through all things, constituting the diverse nature of each one without losing its ultimate unity. The diversity is accomplished by pairing it with a complement, *qi* (in Korean, *ki*), a vital, active, concretizing and hence particularizing component. The unity of *i*, the substance of mind as well as the nature of all things in existence, supported the possibility of cultivating a condition of perfect responsive interrelation with all things, a Confucian sagehood equivalent to Buddhist enlightenment. *Ki*, on the other hand, provided an explanation for imperfection: its various degrees of turbidity or

purity accounted not only for the differentiation of *i* into various levels of nature, but also distorted to varying degrees the otherwise perfect responsiveness of the human mind to its surroundings (see Qi).

The Four-Seven Debate took up the question of the role of this dualism in the issuance of the feelings (see Confucian philosophy, Korean). Spontaneously good responses, such as compassion or the tendency to save a child from danger, seem different from feelings such as anger or desire, which may or may not be appropriate and always need watching. Since the nature (*i*) is normative and *ki* the explanation of disruption, an easy conclusion might be that the reliable feelings (the 'four') arise from *i* while the questionable ones (the 'seven') are rooted in *ki*. This, however, is an extremely dualistic interpretation that ignores the necessary and constant interdependence of *li* and *ki*. Good ethics becomes bad metaphysics. Emphasizing the interdependence, on the other hand, puts all our responsive feelings on exactly the same footing. Neo-Confucian cultivation, and especially meditative practice, set great store on somehow establishing a quiet contact with our purely good deep nature and nurturing the sound tendencies stemming from it. Yi Hwang conceived an approach that recognized interdependence but carved out a distinction between the two sorts of feelings, though this could not settle the question, for there were those who wanted such consistent interdependence that no such variation was satisfactory. Yi Hwang's theory, entirely within the framework of Zhu Xi's thought, was a sophisticated alternative to the radical cleavage that arose in China between the schools of Zhu Xi and Wang Yangming in connection with similar issues.

Yi Kan (1677-1727)

Yi Kan was a major Korean neo-Confucian thinker. He is best remembered as a major protagonist in the Horak controversy where he opposed Han Wônjin, championing the position of the school of Yi Yulgok against Han's novel tri-level theory of nature.

The Horak controversy originated when Han Wônjin stated that even in the state of meditative quiescence, *ki* (in Chinese, *qi*) or 'material force' is present. Neo-Confucian metaphysics is a dualistic monism in which the single *dao* or pattern running through all things is concretized and individualized in real beings only through *ki*. The patterning element, known as *i* (in Chinese, *li*) and often translated as 'principle', also constitutes the innermost nature of all things; its presence as the substance of the human heart-and-mind accounts for our innate potential to respond appropriately to all things and situations (see Li; Qi).

Yi objected strongly to Han's proposition. Metaphysically, it seems the obvious consequence of the interdependence of *i* and *ki*, a theme especially emphasized in the school of Yi Yulgok, to which both Han and Yi Kan belonged. However, in addition to individuation, imperfection or turbidity in *ki* also is a distorting element that accounts for our often imperfect response to things. Han's observation seemed to imply that a quiet criminal is still just a criminal. But in the ascetical life the meditative practice of 'quiet-sitting' was commonly held to obviate the distortion of *ki* and nurture the responsiveness of the heart-and-mind in direct union with its pure, unsullied inner nature. Yi accused Han of violating the authoritative tradition regarding the pure 'original nature' and its role in spiritual cultivation.

Metaphysical theory might favour Han's position, but its implications were intolerable, especially insofar as the major rationale for neo-Confucian metaphysics is to serve as a framework for ascetical theory. In defending conventional ascetical theory and practice, Yi Kan was forced into an unconventional metaphysical position: to make the pure nature accessible without denying the ever-present *ki*, he was forced to introduce the notion that the *ki* of the heart-and-mind is naturally pure; it is only the *ki* that constitutes our physical bodies that is subject to turbidity. In quieting the body and returning to pure objectless consciousness, we enter a level in which *ki* offers no distortion to the nature, which is also the substance or ground of the heart-and-mind. Instead of a dualism of *li* and *ki*, we thus end with a dualism of *ki*. This illustrates the difficulty of accommodating realistically the moral tensions of spiritual practice in the consistently monistic interpretation of Zhu Xi as advocated in Yulgok's school.

In the closely related aspect of the controversy regarding whether the normative nature of all creatures is the same or differentiated according to species, Yi Kan championed the more conventional position against Han's novel tri-level theory of the nature. According to Yi, *i* is normative precisely as considered apart from any (distorting) limitation from *ki*, but *ki* is likewise the source of all differentiation. Hence there is only the unitary *i* of 'the single origin,' and the multitude of concrete individuals, each with their unique *ki* constitution.

There is at present no further information on Yi in western languages.

Yi Yulgok (1536-84)

Yulgok was one of the foremost neo-Confucian scholars in Korea during the Yi (Chosôn) dynasty. He is considered one of two pillars, along with Yi T'oegye, of the Korean neo-Confucian tradition. Yulgok, an active statesman and educator as well as scholar, not only compiled the theories of previous Confucian scholars of China and Korea but, more importantly, developed his own interpretations of them.

Yi Yulgok (real name Yi I; Yulgok was the village to which he retired) was known as a non-dualistic thinker in interpreting the relationship between *i* and *ki*, or 'principle' and 'material force', 'the mind of *dao*' and the 'human mind', 'the four beginnings' and 'the seven feelings'. Yulgok was neither a dualist nor a monist. For example, while he rejected the division between 'principle' and 'material force' on an ontological level, he made a clear distinction between these two concepts on a phenomenological level.

Yulgok's family was intellectually very distinguished: his father came from a long line of Confucian scholar-officials, and his mother, Sin Saimdang, was famous for her intellectual and artistic brilliance. She took Yulgok's education personally in hand and became his first teacher. Yulgok himself was a prodigy. He underwent a long series of civil service examinations, taking the first at the age of thirteen and the last when he was twenty-nine. These examinations opened opportunities to various important functions in the government, and Yulgok performed brilliantly, reaching the very highest official ranks. One examination essay written at the age of twenty-three, *Ch'ôndo ch'aek (A Treatise on the Way of Heaven)*, offered a compelling theory of the unity of heaven and humanity, and it became so important among Confucian scholars of the time that it was eventually carried as far as Ming dynasty China.

Yulgok passed his last civil service examination in 1565. In 1570, he wrote *Tongho mundap (Questions and Answers at Eastern Lake)*, dedicated to the new king Sônjo, with the purpose of instructing him in methods for realizing the ideal Confucian state. An imaginary dialogue between host and guest, cast in a question and answer format, it discusses ways to deal with disordered government, explains 'the way of the ruler' as opposed to 'the way of the subject', and juxtaposes 'the way of the king' with that of the despot. It stresses the importance of the moral cultivation of the ruler himself as a necessary first step towards good government in general. *Tongho mundap* reflects Yulgok's strong social and political concerns, and his horror of the petty political factionalism he encountered at court.

In 1571, while serving as the governor of Ch'ôngju, Yulgok wrote *Sôwôn hyangyak (Community Treaty of Sôwôn)*, a manual on local self-government aimed at teaching local people how to govern themselves. The following year he resigned from the governorship due to illness and retired. At this time he started his famous debate with the Confucian thinker Sông Hon (Ugye) on the interconnected concepts of *i* (principle) and *ki* (material force); 'the four beginnings' and 'the seven feelings'. Yulgok argued that 'the four beginnings' do not contain 'the seven feelings' (or emotions) but the seven feelings (or emotions) do contain the four beginnings. Throughout this debate Yulgok maintained a non-dualistic way of understanding the nature of the relationship between *i* and *ki*; *tosim* (the mind of *dao*) and *insim* (the human mind); and the four beginnings and the seven feelings.

Over the next four years Yulgok also wrote a number of works, addressing issues from practical government to the individual moral cultivation. He compiled *Sônghak chibyo (A Compendium of Sagely Learning)*, selections from the Four Books and the Five Classics - central works of the Confucian canon - grouped around the two themes of moral self-cultivation and proper governance of the people. The choice of selections and their presentation were uniquely Yulgok's own, based on his by then mature grasp of the Confucian and neo-Confucian traditions.

In 1582, Yulgok finished his famous book, *Kyôngmong yogyôl (A Key to Annihilating Ignorance)*, a work which had an enormous and long-lasting influence on Confucian education in Korea. An introduction delineating all the basic elements of Confucian learning and sagely discipline, it was widely used as a textbook for both beginning and advanced students in the Confucian schools. *Yukchokye (The Memorials of Six Articles)*, his last work, was a practical treatise on defence policy, outlining methods for strengthening the kingdom's defences. This work became a central work on the subject, commonly referred to by Yulgok's own slogan, 'nourish and train hundreds of thousands of soldiers'. It was while serving as Defence Minister that Yulgok died of illness in 1584.

As mirrored in his life, Yulgok's thought was divided and moved in two directions. First, there was the study of 'human nature and principle' (*sôngnihak*; in Chinese, *xinglixue*); second, there were the practical considerations of good government. In attempting to relate these two areas of concern - individual self-cultivation and sociopolitical application of the Confucian ideal - Yulgok had to confront on a practical level many of the most pressing political issues of his time: the sixteenth-century Yi dynasty was plagued by countless problems ranging from economics to defence. Yulgok tried to establish a Confucian state by realizing the Confucian social and political ideals through moral self-cultivation.

Yijing

*The Yijing (Book of Changes) or Zhouyi (Changes of the Zhou) was originally a divination manual, which later gradually acquired the status of a book of wisdom. It consists of sixty-four hexagrams (*gua*) and related texts. By the time the Yijing became a coherent text in the ninth century* BC*, hexagram divination had changed from a means of consulting and influencing gods and spirits to a method of penetrating moments of the cosmic order to learn the shape and flow of the* dao *and determine one's own place in it. By doing so, one avoids wrong decisions, failure and misfortune and achieves their contrary. Tradition has it that the Yijing can only be successfully approached through humility, honesty and an open mind. Through interaction with it, one gains ever increasing self-knowledge and sensitivity to one's relations to others and to one's situation in life. 'Good fortune', 'happiness' and 'success' are but by-products of such self-knowledge and sensitivity.*

1 Organization of the *Yijing*

The *Yijing (Book of Changes)* consists of sixty-four hexagrams (*gua*) and related texts. The hexagrams are formed by combinations of two trigrams and result in six solid or unbroken (yang +) and/or broken (yin -lines (*yao*), arranged one above the other in vertical sequence. The combinations are determined by the numerical manipulation of divining sticks, originally yarrow stalks (*achillea millefolium*), or later, by the casting of coins. Each hexagram is accompanied by a hexagram name (*guaming*), a hexagram statement (*guaci*) or 'judgment' (*tuan*), and line statements (*yaoci*) for each of the six lines. The line statements have a sequential organization related to the judgment; each states a specific instance of the judgment, which in complete line statements (many are fragmentary) is followed by an injunction - that one should take some action or refrain from it - and a final determination - 'misfortune', 'good fortune' and so on.

The hexagrams, hexagram statements or judgments and the line statements are the oldest parts of the *Yijing*. Whereas the hexagrams themselves may be much older, the names and statements probably date from the ninth century BC and constitute the first layer in a three-layered text. The second layer consists of another two parts: commentaries on the hexagram statements or judgments called *tuanzhuan* (commentary on the judgments) and commentaries on the abstract meanings or 'images' (*xiang*) of the judgments and the line statements called *xiangzhuan* (commentary on the images). The judgments have 'great images' (*daxiang*) - the abstract meanings of whole hexagrams - and the line statements have 'little images' (*xiaoxiang*) - the abstract meanings of individual lines. These commentaries seem to date from the sixth or fifth century BC and are the first of the exegetical materials in the *Yijing* traditionally attributed to Confucius.

The traditional format of the *Yijing* divides the *tuanzhuan* and the *xiangzhuan* each into two sections. They thus form the first four of the so-called 'Ten Wings' (*shiyi*) of the exegetical material included in the classic. Although all of the 'Ten Wings' are attributed to Confucius, individual 'wings' actually date from different periods, with some earlier and others from as late as the third century BC. However, except for the commentaries on the judgments and the commentaries on the images, which do seem the direct product of Confucius' school if not of Confucius himself, the rest of the 'Ten Wings' consists of later materials, which probably contain reworking of earlier texts. These constitute the third layer of the *Yijing* and include two fragments of an apparently lost commentary on the hexagrams as a whole called the *Wenyan (Commentary on the Words of the Text)*, but only those parts attached to the first two hexagrams - *qian* (pure *yang*) and *kun* (pure *yin*) - survived into the period of textual redaction (early Han era, in the third century BC). The *Wenyan* seems to be a borderline text that contains elements of both the second and third layers. It constitutes the fifth of the 'Ten Wings' and deals with the philosophical and ethical implications of the judgments, line statements and images, all given a Confucian slant.

The sixth and seventh 'wings' are formed by the two sections of the so-called *Xicizhuan (Commentary on the Appended Phrases)* or *Dazhuan (Great Commentary)*. This commentary contains two kinds of material; one deals with the nature and meaning of the *Yijing* in general, and the other is concerned with the meaning of the judgments and line statements of individual hexagrams. The *Xicizhuan* seems to consist of fragments of two different texts, one a general essay or group of essays and the other a collection of specific remarks on individual hexagrams. The eighth of the 'Ten Wings,' *Shuogua (Explaining the Trigrams)* consists of remarks on the nature and meaning of the eight trigrams (*bagua*), the permutations of which form the sixty-four hexagrams. Much here is couched in

terms of *yin-yang* dualism and the theory of the *wuxing* (five elements), and so dates probably from the early Han era (third century BC) (see Yin-yang). It is among the latest of the exegetical materials included. The ninth 'wing' is the *Xugua (Providing the Sequence of the Hexagrams)*, a collection of remarks on each of the hexagrams which attempts to justify their order in terms of etymological and pseudo-rational considerations. This also seems to be quite late material. The tenth 'wing', the *Zagua (Hexagrams in Irregular Order)*, is a collection of brief remarks on the meanings of individual hexagrams, often in terms of contrasting pairs; this is another late addition to the text.

2 History of the text

Traditionally, the hexagrams are thought to have been developed by King Wen of the Zhou in the twelfth century BC, out of the eight trigrams invented by the legendary cultural hero and sage Fu Xi in remotest antiquity. King Wen is also supposed to have composed the hexagram statements or judgements. The line statements are attributed to the Duke of Zhou (d. 1094 BC). However, the assertion that historically identifiable sages are responsible for the origins of the hexagrams and the composition of the first layer of the material is most unlikely. Recent advances in archaeology, paleography and textual studies, which compare the earliest textual layer of the *Yijing* with roughly contemporary inscriptions on bone, shell, metal, stone and other ancient writings that exhibit similar syntax and vocabulary have thoroughly discredited the myth of its sagely authorship. Modern scholarship has also discovered that the original meaning of the judgments and line statements is radically different from what the earliest layer of exegesis took it to be, and often bears little relation to the values of Confucian morality and ethics. Either the writers of the *tuanzhuan* and the *xiangzhuan* were ignorant of this original meaning - being concerned largely with the mechanics of divination and (often) its amoral consequences - or they knowingly suppressed it in order to replace it with a Confucian (or proto-Confucian) reading. However, with this first layer of exegesis the collection of texts, which eventually developed into the *Yijing*, was given a Confucian slant that shaped all subsequent interpretation right up to modern times.

3 The commentary tradition

Although many commentaries on the *Yijing* were written during the Han period (206 BC- AD 220), these were mostly prognostication recipes based on numerological correspondences between the cosmic, natural and human realms (including calendrical considerations) - a so-called *xiangshu* (image and number) approach in which interpreters identified the trigrams and hexagrams with certain standardized images (symbols with fixed meanings). Wang Bi (226-49) broke completely with this and may be said to have written the first philosophical commentary on the *Yijing*; that is, apart from those sections of the work which are themselves commentaries. His *Zhouyizhu (Commentary on the Changes of the Zhou)*, a synthesis of Confucian, Legalist and Daoist views with Confucian views predominant, was extremely influential during the pre-Tang and Tang eras (fourth to tenth centuries AD) and was canonized in the *Zhouyi zhengyi (Correct Meaning of the Changes of the Zhou)* of Kong Yingda (574-648) as the orthodox interpretation of the *Yijing*. Although the commentaries of the later neo-Confucians largely eclipsed Wang's interpretation, much of his commentary was incorporated into the official neo-Confucian orthodox view of the *Yijing*, and what they rejected also helped to shape that view.

A comparison of Wang's commentary with those of Cheng Yi (1033-1107) and Zhu Xi (1130-1200), the most important of neo-Confucian interpretations, reveals how carefully Cheng and Zhu read Wang's remarks and, whether they agreed with him or not (disagreements mostly involve rejection of elements of Legalism and Daoism perceived in Wang's thought), how his arguments tended to shape theirs. Cheng's *Yichuan Yizhuan (Yichuan's Commentary on the Yijing)*, a commentary of textual interpretation (*yili*), explains the work in terms of how the interplay of *yin* and *yang* defines the moral ideals and behaviour of the noble man (*junzi*). Zhu's *Zhouyi benyi (Original Meaning of the Changes of the Zhou)* attempts a reform of the *xiangshu* (image and number) approach combined with neo-Confucian moral interpretation (*yili*): here the *Yijing* is interpreted both as a manual of divination and a book of moral wisdom. Many other commentaries on the *Yijing* were written throughout traditional times, and not only Confucian/neo-Confucian but also Daoist and even Buddhist versions exist. Nevertheless, the most important commentaries were those noted above by Wang Bi, Cheng Yi and Zhu Xi, and most modern annotated editions and translations in Chinese, Japanese, English and other Western languages are based on one or more of these commentaries.

4 The hexagram as discourse

Although later neo-Confucians often disagreed with Wang Bi, they agreed with his general approach to the meaning of whole hexagrams, individual lines and line positions, and the interaction of lines and positions: each hexagram is a unified entity whose 'controlling principle' is expressed in its name and amplified in the hexagram judgement. The controlling principle usually resides in the ruler of the hexagram, one line that is sovereign over all the others. Change occurs because of the interaction between the innate tendency of things and their counter-tendencies to behave in ways opposed to their natures. 'Things' include individual human beings, and the lines of a hexagram represent different kinds of people in different positions and different situations. The action and interaction of lines occur as if people were involved in a particular set of circumstances. Some lines respond to each other and resonate together, signifying harmonious relationships, and some lines repel and clash, signifying opposition and divergence of interests. This resonance or clash produces movement and change, the understanding of which leads to insight into the innate tendencies of things - 'how things are going' - and adjusting one's behaviour accordingly leads to success. Certain hexagrams signify moments of either obstruction or facility and are indicators that one should either refrain from action or engage in it. *Yin* lines are soft and weak; *yang* lines are hard and strong.

The positions of a hexagram are calculated from bottom to top. The odd number places - first (bottom), third and fifth - are strong *yang* positions; the even number places - second, fourth and sixth (top) - are weak *yin* positions. *Yin* and *yang* lines form resonating pairs, and *yin* and *yin* or *yang* and *yang* lines form discordant pairs: the unlike attract and the like repel. Proper resonate relationships can take place between lines of the lower and upper trigrams: one with four, two with five, three with six, but each must pair with its opposite, *yin* with *yang* or *yang* with *yin*. Secondary harmonious relationships can also occur between contiguous lines when '*yang* rides atop *yin*' or '*yin* carries *yang*' but never the reverse, for this is an unnatural, discordant relationship - as when a superior supports or 'carries' his subordinate.

These sixty-four combinations of *yin* and *yang* lines and *yin* and *yang* positions schematically represent all major kinds of situations found in life. One must know how to cast the hexagrams and how to understand the texts of the *Yijing*, for if one can determine which situation prevails at any given moment, what one's place is in that moment and situation and how one relates to the other participants, 'change will yield its all'. As first (bottom) and sixth (top) lines are at the beginning and end points of hexagrams respectively (and thus signify the beginning and ending of situations), they are at the junctures of what precedes and what follows a given situation, and so 'neither of these positions has a constant status'. The other four line positions are either *yang* and 'noble' (three and five) or *yin* and 'humble' (two and four). *Yang* lines 'should' be in *yang* positions and *yin* lines 'should' be in *yin* positions, for this results in hexagrams that generally indicate facility and harmony. Lines 'out of position' (*yin* in *yang* positions, *yang* in *yin* positions) result in hexagrams that generally indicate obstruction and disharmony.

A special role is assigned to the middle positions in the trigrams, positions two and five. These middle positions indicate 'centrality' and 'the mean' (*zhong*), the territory of proper and balanced behaviour and action. The middle position in the lower trigram is a *yin* position (two), and the one in the upper trigram is a *yang* position (five), so very often, regardless of other considerations, the line in the fifth position - whether *yin* or *yang* - is the ruler of the hexagram as a whole, for it is the 'most noble' place, the 'exalted position'.

This approach to the *Yijing* assumes that the casting of hexagrams is an absolutely sure and accurate method of determining the character of moments of time. This is true of all traditional commentators on the *Yijing*: the way that the yarrow stalks or coins fall is indicative of the shape of that particular moment. Everything that occurs in a given moment is interrelated, and all such events share in the same basic character.

Yin-yang

Yin *and* yang *always describe the relationships that obtain among unique particulars. Originally these terms designated the shady side and the sunny side of a hill, and gradually came to suggest the way in which one thing 'overshadows' another in some particular aspect of their relationship. Any comparison between two or more unique particulars on any given topic is necessarily hierarchical: one side is* yang *and the other is* yin. *The nature of the opposition captured in this pairing expresses the mutuality, interdependence, hierarchical relationship, diversity and creative efficacy of the dynamic relationships that are immanent in and give value to the world. The full range of difference in the world is deemed explicable through this pairing.*

Yin and *yang* are elements of a correlative pairing which are pragmatically useful in sorting out 'this' and 'that', and are not, as often claimed, dualistic principles of light and dark, male and female, action and passivity where light and dark both exclude each other and logically entail each other and, in their complementarity, constitute a totality. Rather, *yin* and *yang* are first and foremost a vocabulary of qualitative contrasts which have application to specific situations and enable us to make specific distinctions.

To bring this observation to bear on our understanding of *yin* and *yang*, we must start with the relationship that obtains between any two particular things or events. For example, in a given relationship, 'this' older woman might by virtue of her wisdom be regarded as *yang* in contrast to 'that' younger woman who is *yin*. However, if we were to focus on their fecundity or physical strength, the correlation would likely be the opposite. Important here is the primacy of the particular and the fluidity of the relationship. Although things in this world - that is, particular things - are resolutely hierarchical, no one thing excels in all respects, making this same hierarchy the basis for their complementarity.

In the classical Chinese world, things of the same 'kind' are not defined in terms of their essences as natural kinds but by virtue of their affinity or 'kinship' resemblances that associate them, their 'family resemblances'. Important here is the primacy of particular difference and the absence of any assumed sameness or strict identity. Things are deemed to have resemblances based upon analogous roles or functions. Thus one thing, by virtue of its relationships, evokes many. The suggestiveness of each phenomenon in calling up other similar phenomena is comparable to the multivalence of poetic images. Describing a particular phenomenon does not require the discovery of some underlying determinative and originative principle - a basis for making 'many' one - but a mapping out and an unravelling of the phenomenon's multiple correlations and of the relationships and conditions that make up its context. *Yin* and *yang* define the tension between multiple perspectives on phenomena, and they enable us to interpret and bring coherence to our circumstances by allowing us to discern the patterns in relationships within particular contexts. They provide a vocabulary for sorting out the relationships that obtain among things as they come together and constitute themselves in unique compositions.

Thus, *yin* and *yang* as correlatives are not universal principles that define some essential feature of phenomena, but are explanatory categories that register a creative tension in specific differences and thus make the immediate concrete things of the world intelligible. It is only through a process of generalization that feminine and male gender traits are construed as predominantly *yin* and *yang* respectively, and vocabulary such as vaginal orifice (*yinmen*) and virility (*yangdao*) emerges to essentialize the *yin* and *yang* contrast.

The *yin-yang* vocabulary is functional. In order to evaluate the propensity of a situation and manipulate it in advance, we must make distinctions. This is where the vocabulary of *yin* and *yang* comes into play. We begin from the assumed uniqueness of each situation and the uniqueness of the components that constitute it. The *yin-yang* contrast provides a line, enabling us to divide a continuous situation into distinct yet interdependent particulars. *Yin* is a becoming-*yang*; *yang* is a becoming-*yin*. We must come to know the particular conditions that govern a situation so that we can manipulate them to advantage. This requires that one translate the situation into the *yin-yang* vocabulary of complementary opposites: strong-weak, fast-slow, many-few, regular-irregular and so on. *Yin-yang* is a vocabulary that enables us to discriminate among the many factors which together constitute the force of circumstances, and that allows us to control this force through the strategic adjustments. Once we have arrived at an understanding of the circumstances, we must identify those critical factors which will enable us to turn the configuration of an unfolding situation into an opportunity.

Yoruba epistemology

*The Yoruba of west Africa have articulated systematic criteria that are used to assign varying degrees of epistemic certainty to experience. What one views with one's own eyes and experiences at first-hand (*ìmò*) are judged as reliable ways of knowing the truth, providing there is conscious comprehension of what one is perceiving. Only propositions describing such experiences are regarded as true, or *òótó*. Less reliable is information received via books, other people, the media and the oral tradition. If such comparatively second-hand information, or *ìgbàgbó*, can be experimentally tested and accordingly verified, it has the potential to become *ìmò*. If verification cannot be attested, discussion, analysis and good judgment are essential tools for distinguishing the more reliable information from the less reliable.*

The semantic distinction the Yoruba make between *ìmò* and *ìgbàgbó* serves as a basis for comparison with that between knowledge and belief in traditional Western epistemological theory (see Belief and knowledge §1). Although the Yoruba affirm the epistemic importance of all sensory perception, they single out visual perception, or *ìrirn*, as clearer and more reliable. When conjoined with cognitive comprehension, or *èrí okòn* (literally meaning 'the witnessing of the mind', connoting the conscious processes that arise from both the act of seeing and the sense that one understands what one sees), the two satisfactory conditions for *ìmò*, or knowledge, have been achieved. Experience that satisfies these conditions and propositions that relate such experience, are characterized as being true, or *òótó*. The emphasis placed upon propositions being true because they accurately report experience indicates elements of a correspondence theory of truth (see Truth, correspondence theory of §1).

Ìgbàgbó encompasses all the events and information which do not constitute first-hand experience. This applies to most of what one is taught in the course of a formal education, what one learns from books, the media, other people and, of particular interest in the case of the Yoruba, from the oral tradition. *Ìgbàgbó* is the conflation of 'agree' and 'accept', or *gbà*, and 'hear' and 'understand', or *gbó*. The independent application of negation to its component parts produces four distinct logical possibilities, each of which may be said to correspond to a likely speaker-hearer relationship. These four levels of communication are identified by the Yoruba in the following concrete terms:

(1) *Hearing and agreeing* (p.q): where a hearer, H, understands and accepts as credible what is being reported and therefore, in principle, has no objection to incorporating it into their own store of information. This is optimum communication.
(2) *Hearing and not-agreeing* (p.[thksim]q): H understands what is being offered but declines to accept it as authoritative or correct. Disagreements or lies are offered as standard examples.
(3) *Not-hearing and not-agreeing* ([thksim].[thksim]q): failure to communicate. H does not understand what is being said and therefore cannot agree.
(4) *Not-hearing and agreeing* ([thksim]p.q): in effect, to agree with what one does not understand. Either a case of error or H is described as a fool.

When *ìmò* and *ìgbàgbó* are challenged and an argument or *àríyàn jiyàn* results, the tactics recommended for resolving the dispute are complex and interwoven. Often the disputants do not share the same (relevant) first-hand experiences. This may be corrected by a process of verification so long as it is possible to test the claim empirically and thereby enable people to see the results for themselves: counterclaims about the effectiveness of a certain medicine, for example, can be checked by testing the treatment. When such testing is impossible, there is no way in which the *ìmò* of one person can become the *ìmò* of another. In such a case, the only recourse is to a process of justification. The parties concerned should each explain (*àlàyé*) their own position by giving a full account of relevant first- or second-hand experiences. Any witnesses whose experiences may be relevant should also be called in the hope that their testimony will help decide which account, if any, should be favoured. Such things as the moral character, or *ìwà*, of each participant must be considered, as this might affect the reliability of information.

The aim in this extensive process of justification and evaluation is to lead the various parties to reflect upon and perhaps modify their respective positions, so that agreement may be reached on an accurate account of events, or *papò*, meaning literally 'the word has come together'. Of course it is recognized that, even if the parties concerned

supply full explanations, their moral characters are found to be intact and the testimonies of witnesses are adjudged satisfactory, the dispute may remain unsettled and the argument may continue. In such cases the only realistic alternative is to begin again in the hope that further discussion and reflection may achieve a resolution.

The system that emerges from these criteria is three-tiered. *Imò* is the sole category of experience or propositions permitted to be regarded as both certain and true (*òótó*). *Ìgbàgbó*, which in principle is open to empirical testing, verification and thereby transformation into *ìmò*, is the next most reliable category.*Ìgbàgbó* that can never be verified and can only be evaluated on the basis of explanation, discussion and reflection is the least certain.

Prevalent paradigms describe African traditional thought systems as insignificantly critical or reflective (particularly of the oral traditions, which are said to be the locus of knowledge in such societies), and only marginally empirical because of their emphasis on magic, superstition and secrecy. This account of the ways in which the Yoruba employ and explain key epistemological terms in their language demonstrates that they are more critically- and empirically-minded than had been supposed (see Epistemic relativism §1). The oral tradition, the wealth of knowledge passed down through one's forbears, has not been regarded as an authoritative system of truths. As *ìgbàgbó*, the status of its truth is hypothetical and conditional on being tested or proven practically effective. When proof cannot be obtained, critical discussion and reflection are vital.

You-wu

In the Western metaphysical tradition, 'being' has most generally been thought to denote either a common property of things or a container which relates things by placing them within its own structure. Metaphysical notions of being are generally associated with the concept of ground. By contrast, the Chinese existential verb you *(being) overlaps with the sense of 'having' rather than the copula, and therefore* you *(to be) means 'to be present' or 'to be around' while* wu *(not to be) means 'not to be present' or 'not to be around'. This means that* wu *does not indicate strict opposition or contradiction, but absence. Thus, the* you-wu *distinction suggests mere contrast in the sense of either the presence or absence of* x*, rather than an assertion of the existence or nonexistence of* x*.*

Not a little misunderstanding of classical Chinese thought has been occasioned by the fact that uses of *you* (being) and *wu* (not-being) often seem to echo the speculative understandings of classical Western metaphysics. Thus the Daoist sentiment, often rendered in English as 'Not-being is superior to being,' has given rise to a host of mystical and speculative reflections inspired by the Parmenidean or Heideggerian projects (see Parmenides; Heidegger, M.). In fact, a better translation is simply, 'Nothing is superior to something'. However, even this might suggest presence and absence in some absolute sense. For the Western thinker, an even more accurate translation would be 'Not-having is superior to having': or as a contemporary Chinese Marxist translation reads, 'Not-owning is superior to owning'.

It may be said that the proper understanding of 'being' in the Chinese tradition, more than any other philosophical concept, depends upon the ability to suspend predispositions deriving from Western philosophical sources. For, without recourse to the senses of being associated with Western speculative philosophies (see Being), and in the absence as well of the sophisticated logical apparatus employed by the nominalistic traditions in contemporary thought, the interpretative contexts familiar to Western trained thinkers are simply not relevant. Thus the Chinese discussions of the *you-wu* relation must not be thought to be 'metaphysical', if we mean by metaphysics anything like a universal science of principles or of being-itself. Nor may we be allowed to interpret 'being' and 'not-being' by recourse to logical operators associated with modal or truth-functional logics (see Modal logic).

Thus when the Chinese discuss cosmological issues of the sort that require an understanding of kinds of existing things, or the basic categories that make up the world as we know it, we must proceed with caution. While it is true that Chinese thinkers, particularly the Daoists, ask about things, they do not ask about 'categories' or 'kinds' in any manner that would suggest that things have 'logical essences' or constitute 'natural kinds' (see Essentialism).

The principal reason Chinese thinkers are not apt to ask after the *logos* of the cosmos is that they lack an operative sense of cosmos or 'world' as a coherent whole. Their sense of *logos* - *li* (pattern) - is a radically situated notion (see Li). In fact, the Chinese understanding of 'cosmos' as 'the ten thousand things' means that, strictly speaking, they have no concept of cosmos at all insofar as that notion entails either a coherent, single-ordered world or a congeries of entities with essential features or essential modes of connectedness. The Chinese are therefore primarily 'acosmotic' thinkers.

In the absence of a sense of being as the ground of things, the act of understanding and articulating the sense of things - *daoli* (the grasp of the patternings (*li*) of *dao* (the ways of things)) - cannot have ontological reference (see Dao). The closest to our typical understanding of 'reason' or 'reasoning' is to be found in 'seeking the *li*'. *Wulixue* in modern Chinese is 'the investigation of the patterns of things and events', what we term 'physics'. 'Psychology' is *xinlixue*, 'the investigation of the patterns of the heart-mind'. In general, to be *heli*, to be in accord with *li*, is to be reasonable or rational (see Li; Confucian philosophy, Chinese).

The translation of *li* as 'principle' has created some confusion in the minds of Western interpreters of Chinese, many of whom just assume that *li* must, at some level, be transcendent. But *li*, as a 'making sense of things', cannot be understood as a process of seeking principles as determining sources of order, or of discovering essential categories inclusive of particular things. It is, rather, an activity which constructs categories (*lei*) analogically, then traces, again by analogical means, correlated details which manifest patterns of relationships immanent within things and events. This sort of reasoning depends upon noninferential access to enlarged and deepened patternings.

Inclusion or exclusion of items within a ‘category’ are never associated with notions of logical ‘type’ or ‘class’. The sortings are analogical, not logical. This understanding of ‘reason’ and ‘reasoning’ is one more implication of the fact that the Chinese never asked ‘the question of being’.

Zabarella, Jacopo (1533-89)

Jacopo Zabarella was a professor of philosophy at the University of Padua. His work shows conclusively not only that it was possible to philosophize creatively within the limits of the Aristotelian tradition but also that this was still being done towards the end of the Renaissance period. Zabarella's aim was not to overthrow Aristotle's doctrines, but to expound them as clearly as possible. He produced an extensive body of work on the nature of logic, arguing that it was neither an art nor a science, but rather an instrumental intellectual discipline which arose from the philosopher's practice of philosophizing or forming secondary notions. He also worked extensively on scientific method. He gives an account of order as disposing what we come to know through method, and he divides method into the method of composition, which moves from cause to effect, and the method of resolution, which moves from effect to cause. He also discussed regressus *(a method for uniting composition and resolution) and thought that it would enable the scientist to discover new causal relations at the same time as proving conclusions with absolute necessity. Zabarella's work was instrumental in a renewal of natural philosophy, methodology and the theory of knowledge; and it had a major impact on seventeenth-century philosophy textbooks, especially in the Protestant countries of northern Europe.*

1 Life

Count Jacopo (or Giacomo) Zabarella seems never to have left his native city, Padua. He enjoyed a thorough education, receiving his doctorate in philosophy and the liberal arts in 1553, and began his teaching career in 1564 when he obtained the first chair of logic. In 1568 he obtained the second extraordinary chair of natural philosophy, and was promoted to the first extraordinary chair of natural philosophy in 1577. Finally, in 1585, Zabarella obtained the second ordinary chair of natural philosophy, which he held until his death. Padua was a leading university, and Zabarella was taught by some of the best teachers there: Francesco Robortello in the humanities, Bernardino Tomitano in logic, Marcantonio Genua in physics and metaphysics, and Pietro Catena in mathematics. His academic career was exemplary for a Paduan professor of philosophy, with two exceptions. First, the statutes of the university prevented him, as a native Paduan, from obtaining the first ordinary chair in natural philosophy; second, he never took a degree in medicine, perhaps through his own choice. His publications reflect his teaching in the Aristotelian tradition. From 1578 to 1584, he published on logical problems, including a commentary on the *Posterior Analytics*. In 1590 he published a volume of questions in the contemporary Aristotelian manner, which contained 30 books and followed the traditional order of Aristotle's works on nature. These were supplemented by commentaries on the *Physics*, *On Generation and Corruption*, *On Meteors* and *On the Soul*.

2 The nature of logic

Zabarella's introductory treatise on the nature of logic, *De natura logicae (On the Nature of Logic)*, is basic to his teaching in logic (see Logic, Renaissance §1). He defines logic as being neither a science nor an art, but, in keeping with the traditional meaning of the word 'organon', just an instrument of the arts and sciences. Logic does not have a real subject of its own, but deals with concepts, which stand for real beings. In this it is comparable to grammar. The difference between grammar and logic is that grammar is concerned with the perfect verbal expression of concepts, and hence is a linguistic discipline (*disciplina sermocinalis*), while logic invents second notions (*notiones secundae*, often called second intentions), that are able to create order among concepts, and serve to recognize the truth and distinguish it from falsehood in every instance. Logic is thus a rational discipline (*disciplina rationalis*). It is not itself philosophy, but springs from philosophy and is devoted to philosophical ends.

Zabarella followed Averroes in dividing logic into two parts: universal logic, which is common to all subjects; and particular logic, which is specific to particular subjects. The first three books of Aristotle's Organon, the *Categories*, *De Interpretatione* and the *Prior Analytics*, constitute universal logic. Aristotle's *Posterior Analytics*, *Topics* and *Sophistical Refutations* are said to deal with particular logic, in that they deal respectively with the demonstrative syllogism, the dialectical syllogism and the sophistical syllogism (see Aristotle §1). Following the Neoplatonic commentators Simplicius and Ammonius, Zabarella included Aristotle's *Rhetoric* and *Poetics* in logic. The former is included because it teaches the use of the rhetorical syllogism or enthymeme, and rhetorical induction or example; the latter because it also teaches the use of example, not to persuasive ends, but for imitation. It has been argued that Zabarella here paved the way for modern aesthetics.

3 Arts and sciences

Since logic, viewed as the universal instrument for distinguishing between the true and the false, differs according to the objects to which it is applied and the ends for which it is used, its nature depends on the realm of possible objects and ends. Rhetoric and poetics are special cases because they deal not with knowledge but with the political disciplines (*disciplinae civiles*) in so far as they are concerned with the good of the people. Sophistical syllogistic is another special case, because it is directed towards deception and prefers to use falsehoods as its material. Dialectic and demonstration, however, are directed towards the expression of truth. Dialectic is aimed at the production of opinion, and deals with probable and contingent material; demonstration is dedicated to the acquisition of truth, and so is exclusively occupied with necessary, true objects. As a result the sciences in the proper sense of that term, as pertaining to demonstrative knowledge, are limited to those disciplines that deal with the necessary and eternal or with what can be deduced from necessary principles. These disciplines are the contemplative sciences, metaphysics, mathematics and physics. The necessity involved is both ontological, with respect to the objects known, and cognitive, with respect to the knowing subjects.

All the other so-called arts and sciences deal with contingent objects, that is, with objects which depend on our volition and are therefore either actions, as in the case of the moral disciplines, or artificial beings generated by our productive faculties, as in the case of the arts in the proper sense of that term. The arts as arts are unable to generate true knowledge rather than mere opinion, except where inferences from the desired ends to the necessary means are concerned.

Given this distinction, Zabarella presents the contemplative sciences as being the only defenders of true knowledge. However, by describing the arts in terms of their specifically productive character, he secures for them the autonomy of modern technical disciplines. The use made of Zabarella’s discussion in the textbooks of seventeenth-century Protestant countries prove this seemingly traditional Aristotelian division to have been fruitful.

4 Method

The instrument for acquiring knowledge in the broadest sense is method. Since knowledge can be acquired either through teaching or through invention, Zabarella distinguished between two kinds of method: *ordo doctrinae*, which is the order of teaching, and *methodus* in the narrow sense, which is the method of finding new knowledge. Both involve leading the way from something known to something hitherto unknown. *Methodus* does this by the inference of new items of knowledge; *ordo* does it by the disposition of items already known to the teacher. Neither procedure is governed by the nature of the objects known, but by the nature of human knowledge. *Methodus* starts with what is better known to us, which can be the cause for further cognition, rather than with the better known in itself, which can be the cause of a known object. *Ordo* starts with what is either necessary or useful for teaching and learning. In the contemplative sciences, which aim at perfect knowledge, *ordo* follows the so-called way of composition (*compositio*) from general principles to particular beings; in moral philosophy and the arts, which aim at action or production, *ordo* follows the so-called way of resolution (*resolutio*) from the desired end to its first principles. The bitterly polemical reaction of Zabarella’s contemporaries, especially his colleague Francesco Piccolomini, to this grounding of method and order on cognitive rather than ontological principles, shows how revolutionary his approach seemed at the time.

5 The method of *regressus*

Although, given their concern with perfect knowledge, the contemplative sciences cannot do without the deductive procedures of composition, they also depend on the inductive procedures of resolution, at least in the case of physics, where the particular beings or effects are better known to us.

The so-called method of *regressus* is a model for combining both procedures that is found in the Aristotelian tradition from Averroes on, and was revived during the Italian Renaissance. According to this method, the natural philosopher should first infer from the known effect the existence of the cause of the effect. This is the so-called *demonstratio quia* or demonstration of the fact. Then in a second step, in the so-called *demonstratio propter quid* or demonstration of the reasoned fact, the natural philosopher should infer from the cause to the effect, which is now known through its cause, and hence in a scientific manner. The crucial problem with this procedure is how to avoid mere circular reasoning, or rather, how to make sure that the cause, whose existence is demonstrated in the

first step, is indeed the cause of that effect. From the beginning of the sixteenth century, it had become clear that it was necessary to introduce a third, intermediary step, which involved some kind of *negotiatio intellectus* or intellectual operation. How the intellect did this was a matter of dispute.

Zabarella himself solves the problem of the *negotiatio intellectus,* which he calls a mental examination (*examen mentale*) in terms of his psychology of knowledge. Since for him the task of this intermediary step is to make distinct the confused knowledge of the cause that was acquired through the first step, he refers to his work on the agent mind in which he develops an account of the transformation of confused into distinct knowledge through the analysis of a given whole in terms of its parts. He presents this process as the specific ability of the human mind. Thus once more method as a means for acquiring knowledge is based on the cognitive structure of the knowing subject rather than on the ontological structure of the object of knowledge. This foreshadows the substitution of epistemology for metaphysics in much modern philosophy.

6 Natural philosophy

Natural philosophy, which deals with corporeal beings that have an inner principle of movement, differs from metaphysics (which contemplates being as being) and from mathematics (which deals with abstracted beings), both with respect to the object considered (*res considerata*) and with respect to the way of considering (*modus considerandi*). As a result, it is autonomous and independent of both the other contemplative sciences. It has to know and teach the very essence of natural beings. First, it has to deal with their basic principles, such as matter and motion, which are not natural beings themselves. They are discussed in Aristotle's *Physics*. Second, it has to deal with the accidents of natural beings understood through their causes. These are the subject of Aristotle's other writings on nature, from *On the Heavens* to *On the Soul*. Generally speaking, Zabarella saw natural philosophy as developed by Aristotle as complete according to the scope of its subject matter as well as in its manner of consideration. His main emphasis is therefore on teaching, for invention is only needed in the rare case of a gap in the Aristotelian corpus (see Natural philosophy, medieval).

In spite of its empirical basis, Zabarella's natural philosophy is not concerned with anything akin to experiment. Indeed, if experiments were to be developed, they would find their place in the productive arts rather than in natural philosophy. Nor was he concerned with the role of mathematics in scientific procedure. However, attempts have been made to link him with Galileo. For instance, Randall (1961), following Cassirer, referred to the Renaissance discussion of *regressus* up to Zabarella as a preparation for Galileo's new method of natural science. This hypothesis has been widely debated but remains problematic.

Zeami (1363-1443)

Zeami was one of the leading innovators in the art of Nō*, at a time when Zen Buddhism dominated the Japanese intellectual and cultural order. He practised Zen Buddhism (Sōtō branch), and found in Zen teachings the epistemology that gave* Nō *its aesthetic foundations. While his* Nō *treatises are buttressed by his observation of the nature and the workings of the mind, they also reveal Shintō sensibility in their view that the origin of entertainment is sacred.*

Nō (or *noh*) is a theatrical entertainment which mixes singing and dance movements by actors (the main actor usually wears a mask), accompanied by a chorus and musicians. Zeami (real name Kanze Motokiyo) became the head of the Kanze-za, a prominent *Nō* troupe. He composed or reworked at least sixty *Nō* plays, directed and choreographed them, trained his sons as *Nō* actors and playwrights, wrote *Nō* treatises for them, toured with his troupe and entered *Nō* competitions on various occasions.

A passage in the treatise *Kakyō (A Mirror Held to the Flower)* illustrates how Zeami gave his attention to the mental and psychological aspects of *Nō* performance. He discusses several essential practices for the *Nō* actor. For instance, in order to move the audience, he advises that an actor first enunciate his line and then follow with a physical movement. It is more effective for an actor to sing, ‘I cry’, and then move his arm to cover his face to express that gesture, than it is for him to cover his face and then sing ‘I cry’. Zeami explains that in the latter case the actor’s words would have no lingering effect. He holds that this slight staggering of the auditory and visual inputs is crucial in creating an artistic effect.

Zeami places at the foundation of his art the same development of mental awareness that is sought in Zen Buddhism (see Buddhist philosophy, Japanese). In *Kakyō*, he notes that to achieve a graceful appearance, the actor must see what is at his right, left and in front of him with his physical eyes, but he must also train himself to see himself from behind with his mind. Zeami terms this ability to see what the physical eyes cannot see *riken no ken* (seeing separate [from an ego-bound mode of] seeing). The cultivation of this mental capacity, which transcends our ego-centred perspective, requires of the actor a conscious training of his mind. Zeami does not say outright that a *Nō* actor must go through meditation practice as a Zen monk, but he seems to maintain that the mental practice involved in *Nō* training and Zen practice is one and the same. Through his assiduous practice and training, the *Nō* actor will eventually have to attain awakening (*satori*), just as a Zen monk must, and he then must further incorporate his awakening into his performance. Zeami warns his sons that expert spectators also see into the accomplishment of the actor and his performance with their *riken no ken*. Thus, it is essential for the actor to develop his *riken no ken* to take account of even the critical eyes of the spectators.

Because of the homogeneity of the mindset required of the *Nō* actor and Zen practitioner, the aesthetic hierarchy of *Nō*, at least at the time of Zeami, was heavily informed by Zen taste. Accordingly, what Zeami terms the higher sort of plays or performances do not consist of surface beauty that merely please eyes and ears. Rather, they comprise plays and performances that possess an ethereal beauty like that of the heavenly maiden, or which can be compared to ‘white plum blossoms’ or the ‘icy quality’ of ‘snow piled up in a silver container’. According to Zeami, this sort of beauty is pure, beyond any conscious manipulation of mere technique, and evokes deep emotional resonance in the minds of the audience (see the *Kakyō*, *Kyūi (Notes on the Nine Levels)* and *Shūgyoku tokka (Finding Gems and Gaining the Flower)*).

Zeami could not neglect Zen partly because the Shogun Yoshimochi (reigned 1408-28) patronized it. However, Shintō sensibility was also inherently present in his formation of *Nō* as a distinct genre of art. For instance, Zeami ascribes one of the origins of *Nō* to the Shintō account of the ‘incident of the heavenly rock cave’, in which the Sun Goddess Amaterasu hid herself inside a rock cave and the entire world became dark. Ama no Uzume, a goddess, performed a shamanic dance in a trance and aroused the other deities present. The uproarious noise these deities made brought Amaterasu out of the cave; the world became bright again, and the gods’ faces (*omo*) shone ‘white’ (*shiro*) in the bright light. In the *Fūshi kaden (Teachings on Style and the Flower)* Zeami subscribes to this traditional etymology of the word *omoshiro* (delightful or interesting).

We find in Zeami’s treatises penetrating psychological insights, an applied Zen epistemology and vibrant religious

sensibility. All of these contributed to his articulation of the art of *Nō* as a path of self-awakening and a god-inspired entertainment that gives pleasure to the people.

Zeno of Citium (334-262 BC)

Zeno of Citium, a Greek philosopher from Cyprus, founded the Stoic school in Athens c.*300 BC. His background and training lay in various branches of the Socratic tradition, including the Platonic Academy, but especially Cynicism. His controversial Republic was a utopian treatise, founded on the abolition of most civic norms and institutions. He laid the main foundations of Stoic doctrine in all areas except perhaps logic.*

Zeno was born at Citium, a town in Cyprus of mixed Greek and Phoenician culture. His father, a merchant, used to bring copies of Socratic dialogues back from his visits to Athens. It was perhaps these that inspired Zeno, at the age of 22, to move to Athens and study philosophy in the milieu in which Socrates himself had lived.

Zeno chose a series of teachers representing different branches of the Socratic tradition, starting with the Cynic Crates. Cynic ethics (see Cynics) remained a dominant influence on his thought. Polemo, the head of the Platonic Academy, (see Platonism, Early and Middle §§1,8) and the Megarian philosopher Stilpo (see Megarian School) were among his other teachers, and both will have supplied a primarily ethical orientation as well, although with some input of metaphysics. Stilpo's most celebrated doctrine was the self-sufficiency of the wise. Finally Diodorus Cronus, whose classes he attended along with the future logician Philo, represented the dialectical side of the Socratic tradition, offering Zeno a training in logic as well as in the study of sophisms (see Philo the Dialectician).

In time - around the turn of the century - Zeno formed his own philosophical group, at first known as Zenonians but eventually dubbed 'Stoics' after the Painted Stoa in which they used to congregate. Zeno remained in Athens until his death in 262 BC, and the school he had founded became the dominant school of the Hellenistic age.

Zeno was more an inspirational than a systematic philosophical writer, and later generations took on the task of formalizing and developing his philosophy. The most provocative of his twenty-seven recorded works - reported also to be his first - was a utopian political tract, the *Republic*, whose title echoes those of like-named works not just by Plato but also by the Cynic Diogenes of Sinope. Its exact character is disputed. Some fragments suggest a cosmopolitan theme, anticipating and no doubt inspiring the later Stoic conception of the cosmic city (see Stoicism §18). But many others make it clear that its main proposals were for the radical reform of a single political community. In characteristically Cynic fashion, most civic institutions - temples, law courts, coinage, differential dress for the sexes, conventional education, marriage, and so on - were to be abolished. The city was to be a community of the wise, united by concord and, it seems, a sublimated form of erotic love. Some later Stoics found this work so deeply embarrassing that they branded it, or parts of it, as spurious. However Chrysippus, his second successor, wholeheartedly defended its proposals and tenets.

Despite the controversy surrounding his *Republic*, Zeno undoubtedly established, often against tough opposition, the main canonical positions of Stoic ethics, epistemology and physics. His most distinctive ethical innovation was the insistence that moral indifferents like wealth and poverty could be placed in a natural ranking order of preferability. In developing it he faced resistance on the one side from his former Platonist teacher Polemo, who insisted that such a ranking must be a moral one, in terms of relative goodness, on the other from his colleague Ariston of Chios (§2) who denied that any differentiation between 'indifferents' was possible. His epistemological thesis that certainty can be attained through the senses was persistently challenged by the New Academy (see Arcesilaus §2) and adjusted to meet the criticisms. He approved of dialectic mainly as a defence against the sophistries of others, and is not known to have made any major contribution of his own to Stoic logic.

In some areas it was less his doctrines than his daring style of argument that forced later Stoics to rally to his defence. The flavour can be glimpsed from two of his more controversial syllogisms. 'It would be reasonable to honour the gods; it would not be reasonable to honour the non-existent; therefore the gods exist.' 'Voice comes through the windpipe; if it were coming from the brain, it would not come through the windpipe; where speech comes from is where voice also comes from; but speech comes from the mind; therefore the mind is not in the brain.' (This latter argument obliged Chrysippus and other Stoics to fight a rearguard action against the latest anatomical discoveries.)

Zeno of Elea (*fl. c.*450 BC)

The Greek philosopher Zeno of Elea was celebrated for his paradoxes. Aristotle called him the 'founder of dialectic'. He wrote in order to defend the Eleatic metaphysics of his fellow citizen and friend Parmenides, according to whom reality is single, changeless and homogeneous. Zeno's strength was the production of intriguing arguments which seem to show that apparently straightforward features of the world - most notably plurality and motion - are riddled with contradiction. At the very least he succeeded in establishing that hard thought is required to make sense of plurality and motion. His paradoxes stimulated the atomists, Aristotle and numerous philosophers since to reflect on unity, infinity, continuity and the structure of space and time. Although Zeno wrote a book full of arguments, very few of his actual words have survived. Secondary reports (some from Plato and Aristotle) probably preserve accurately the essence of Zeno's arguments. Even so, we know only a fraction of the total.

According to Plato the arguments in Zeno's book were of this form: if there are many things, then the same things are both F and not-F; since the same things cannot be both F and not-F, there cannot be many things. Two instances of this form have been preserved: if there were many things, then the same things would be both limited and unlimited; and the same things would be both large (that is, of infinite size) and small (that is, of no size). Quite how the components of these arguments work is not clear. Things are limited (in number), Zeno says, because they are just so many, rather than more or less, while they are unlimited (in number) because any two of them must have a third between them, which separates them and makes them two. Things are of infinite size because anything that exists must have some size: yet anything that has size is divisible into parts which themselves have some size, so that each and every thing will contain an infinite number of extended parts. On the other hand, each thing has no size: for if there are to be many things there have to be some things which are single, unitary things, and these will have no size since anything with size would be a collection of parts.

Zeno's arguments concerning motion have a different form. Aristotle reports four arguments. According to the Dichotomy, motion is impossible because in order to cover any distance it is necessary first to cover half the distance, then half the remainder, and so on without limit. The Achilles is a variant of this: the speedy Achilles will never overtake a tortoise once he has allowed it a head start because Achilles has an endless series of tasks to perform, and each time Achilles sets off to catch up with the tortoise it will turn out that, by the time Achilles arrives at where the tortoise was when he set off, the tortoise has moved on slightly. Another argument, the Arrow, purports to show that an arrow apparently in motion is in fact stationary at each instant of its 'flight', since at each instant it occupies a region of space equal in size to itself. The Moving Rows describes three rows (or streams) of equal-sized bodies, one stationary and the other two moving at equal speeds in opposite directions. If each body is one metre long, then the time taken for a body to cover two metres equals the time taken for it to cover four metres (since a moving body will pass two stationary bodies while passing four bodies moving in the opposite direction), and that might be thought impossible.

Zeno's arguments must be resolvable, since the world obviously does contain a plurality of things in motion. There is little agreement, however, on how they should be resolved. Some points can be identified which may have misled Zeno. It is not true, for example, that the sum of an infinite collection of parts, each of which has size, must itself be of an infinite size (it will be false if the parts are of proportionally decreasing size); and something in motion will pass stationary bodies and moving bodies at different velocities. In many other cases, however, there is no general agreement as to the fallacy, if any exists, of Zeno's argument.

1 Life and works

Information about Zeno's life is scarce. Plato (§15), in his *Parmenides*, reports a visit to Athens by Zeno, in the company of Parmenides, usually dated around 450 *bc*. Zeno was then in his late thirties, a younger contemporary of Parmenides who was then in his mid-sixties. He had associated with Parmenides for some time. By the time of this visit Zeno had already produced a book, the reputation of which preceded him to Athens. Diogenes Laertius writes about Zeno's courage and his political activities, detailing some unreliable stories about his heroic death at the hands of a tyrant.

Reliable information about Zeno's writings is equally paltry. Some of his arguments have been saved verbatim

(mainly those concerning plurality); others have survived only via brief reports (mainly those concerning motion). In most cases, the arguments are baldly stated, and some effort is required to reveal their strength and structure.

2 The arguments against plurality

There is no universal agreement on what Zeno hoped to achieve with his arguments. The orthodox view, stemming from Plato, is that Zeno's purpose was to defend Parmenides' monism, which denied the reality of both plurality and motion. Zeno defended Parmenides by attacking those opponents who mocked his position. This view of Zeno has two consequences. First, Zeno's arguments are *ad hominem*: so, while Zeno's opponents should be committed to any assumptions they involve, those assumptions need not be endorsed by Zeno himself. Second, the Parmenidean position should, ideally, be immune to the destructive force of Zeno's arguments.

Monism, the view that only one thing exists, is not very plausible. An intuitively more attractive position is pluralism:

(1) The world contains more than one thing.

Pluralists differ from one another as regards *which* things the world contains. We do not know which pluralists Zeno was attacking. Some have argued for a philosophically sophisticated target - for example, Pythagoreans - but this is now widely rejected. A more appealing denial of monism is an unsophisticated pluralism. 'Simple pluralism' is the common-sense view which holds both (1) and

(2) These things are ordinary objects such as horses, human beings, oaks,…

According to the sixth-century philosopher Philoponus, Zeno's target was simple pluralism:

> Those who introduce plurality put their confidence in its self-evidence; for there exist horses and people and a variety of individual things, and the aggregation of these produces plurality. This self-evidence therefore Zeno tried to overthrow…
>
> (*On Aristotle's Physics* 42.18-21 in Lee 1936: §8)

Zeno's challenge to simple pluralism is successful, in that he forces anti-Parmenideans to go beyond common sense. Post-Zenonian atomism (see Atomism, Ancient; Democritus §§2-3), for example, conjoins (1) not with (2) but with

(3) These things are indivisible masses of atomic stuff moving in empty space.

Aristotelian pluralism retains (2), but only by working out a far more sophisticated understanding of what constitutes a unity than is provided by common sense (see Aristotle §§11-14)).

Several of Zeno's arguments rely on a pluralist's accepting that any magnitude can be divided infinitely many times. However, Parmenides' One would not be vulnerable to these arguments, because the only premise concerning infinite divisibility that the arguments require is

(ID) If anything at all is divisible, then whatever is extended is divisible.

Since Parmenides (§5) held that there is nothing which is divisible, the conditional (ID) would pose no threat for him. Simple pluralists, by contrast, think that the whole is divisible - that is what makes them pluralists. (ID) relies on the thought that there is something objectionably arbitrary in a world which is a homogeneous and continuous mass of existing things being divisible, but only up to a certain point: being divisible just this far (into horses and oaks,…) but no further (not, for example, into horse bits and oak bits). Subsequent pluralists could nevertheless evade Zeno's arguments by denying (ID), as the atomists did; Democritus denied the homogeneity of the world, by introducing two quite distinct types of real entity - atoms and void. In such a case (ID) is no longer plausible, since an explanation can be provided of why the world should be divisible into atoms and no further (see Democritus §2).

It should be noted, however, that Plato's interpretation of Zeno as supporting Parmenides is not mandatory. Eudemus, the pupil of Aristotle, read him as attacking not only pluralities but also Parmenides' One, and this alternative view of Zeno as a nihilist, rather than a monist, gained some currency (Seneca, *Letters* 88.44-5).

3 The ‘limited and unlimited’ argument

The ‘limited and unlimited’ argument is fragment 3. It is preserved by Simplicius, and appears to be a direct quotation from Zeno.

[(A)] If there are many things, it is necessary that they are just as many as they are, and neither more nor less than that. But if they are as many as they are they will be limited.
[(B)] If there are many things, the things that are are unlimited; for there are always others between the things that are, and again others between those. And thus the things that are are unlimited.

(A) is a strong argument, granted a false, although very appealing, assumption. Suppose

(A1) There are many things [call them the totality T].

Then

(A2) It is necessary that they are just as many as they are [T contains exactly as many items as T]
(A3) and neither more [T does not contain as many items as T^{+}, which contains everything T contains, along with some extra items] nor less [T does not contain as many items as T^{-}, which contains almost everything T contains, apart from some items].

So

(A4) If they are as many as they are they will be limited [the content of T is limited to just so many items, in contrast to the number in T^{+} or the number in T^{-}].

This argument requires the assumption

(A5) If T^{*} contains everything that T contains, along with some extra items, then T^{*} contains more items than T and T contains fewer items than T^{*}.

(A5) is extremely appealing: for it can seem that T^{*} *must* contain more items than T, just because it is T with some extra items added. But (A5) is false. It claims that if T is a subset of T^{*} then T and T^{*} do not contain the same number of items, and that is not unrestrictedly true: it is false if T and T^{*} each contain infinitely many things (see Infinity §6).

The other half of Zeno’s argument, (B), shows in contrast that (A4) fails for any totality of units comprising the simple pluralists’ world. (B) provides a method for adding extra items to any specification of T, and so expanding it into a totality T^{+}, which according to (A5) contains more items than T.

The method Zeno provides for expanding T into T^{+} is this: *there are always others between the things that are, and again others between those*. Suppose T is specified as this horse, that human being, the oak over there… (B) concentrates attention on the claim that this horse and that human being, for example, are distinct units. A simple intuition lies behind including this horse and that human being within T: namely, that they are distinct units because there is something else between them - for example, this saddle. But an obvious question then arises: what makes this saddle and this horse distinct units? Zeno envisages two possible answers. First, that they too are distinct because there is something else between them - for example, this horse blanket. Second, that they are distinct even though they are in contact. If the simple pluralist offers the first answer, a method of expanding any specification of T follows immediately (since the next question to arise will be: what makes this saddle and this horse blanket distinct items?). If the second answer is offered, another expansion method suggests itself. If this horse and this saddle can be distinct units, even though they are in contact, then why not say, by parity of reasoning, that this leftmost horse chunk and that rightmost horse chunk are distinct units? In either case (A4) fails to hold: any specification of T can be expanded into a totality containing extra members.

It is necessary to go beyond the resources of simple pluralism to respond to this argument. Zeno assumes that his opponents view the world as a homogeneous and continuous mass of existing things. In the absence of absolutely basic differences between things, the only way to pick out units will be by their relations to one another - for

example, by their being spatially discrete. (B) is a cogent argument against that position. One response would deny the assumption of homogeneity. Democritus was able to identify units because his world contained atomic stuff and void as two fundamentally different types of entity. Any two atoms are distinct because they are separated from one another by void, while an atom and the void surrounding it are distinct because they are intrinsically different. But to resist Zeno's argument by making that move is to abandon simple pluralism. Democritus' world is not a plurality of horses and human beings, but of atoms. A deeper response would involve a more sophisticated view of units and pluralities: for example, the Aristotelian ontology of substantial unities rehabilitates entities like this horse and that human being and picks them out as units in terms of their functional organization (see Aristotle §13).

4 The 'large and small' argument

The 'large and small' argument can be found in fragments 1 and 2, which consist of material quoted by Simplicius in his commentary on Aristotle's *Physics* (he reports Zeno's 'limited and unlimited' argument in the same pages). Simplicius reports three different sub-arguments, contributing to a single Zenonian argument: that if there is a plurality, the same things will be 'large' (of infinite magnitude) and 'small' (of no magnitude).

According to Simplicius (in fr. 2.17-18), Zeno argued that the units of a plurality would have *no* magnitude by means of the following argument:

[(C)] It has no magnitude since each of the many is the same as itself and one.

Argument (C) requires three premises, including (ID) (see above):

(C1) If there is a plurality there must be units *which are not themselves pluralities*.
(C2) Whatever is divisible is *ipso facto* a plurality.

According to the simple pluralist there is a plurality. So given (C1) there must be non-plural units. But those units cannot have magnitude. For according to (ID), if they had magnitude, they would be divisible, in which case according to (C2) they would themselves be pluralities, contrary to (C1). So (ID), (C1) and (C2) imply that any unit (anything that is *the same as itself and one*) will have no magnitude. Argument (C) is valid. The way to evade the argument is to deny one of its premises. The atomists deny (ID), while denial of either (C1) or (C2) augurs a more sophisticated understanding of the relation between unity and plurality.

Before giving Zeno's argument for the conclusion that the units of a plurality must have unlimited magnitude, Simplicius (fr. 2.8-14) reports a Zenonian argument that what has no magnitude does not exist:

[(D)] For if it were added to something else that exists, it would make it no larger; for if it were of no magnitude, but were added, the thing it was added to could not increase in magnitude. And thus what was added would in fact be nothing. If when it is taken away the other thing is no smaller, and again when it is added will not increase, it is clear that what was added was nothing nor again what was taken away.

Adding what has no magnitude (for example, a point) to something would not increase its magnitude, and so would be tantamount to adding nothing. Zeno concludes that what has no magnitude would *be* nothing, and so would not exist. It seems, however, that Zeno's argument will inevitably be question-begging. Imagine adding an electric charge to a metal sphere: the sphere's *magnitude* will not be increased, but adding an electric charge is not tantamount to adding nothing, since the addition may greatly affect the sphere's behaviour. Zeno's conclusion would follow from the assumption that the only significant differences are differences in magnitude: but that assumption is worryingly close to the conclusion Zeno wants to establish by argument (D), namely:

(D1) Whatever exists has magnitude.

Still Zeno's endorsement of (D1) would be consistent with his defending Parmenides, according to whom what exists is apparently spherical in shape (see Parmenides §8). What is more interesting than the argument for (D1), however, is the way in which Zeno uses argument (D) in order to show that the units of a plurality will be of unlimited magnitude.

Fragment 1 gives the argument for this conclusion, which Simplicius puts in Zeno's own words.

For having first proved [(D) above] that if what is had no magnitude it would not even exist, [Zeno] goes on

[(E)] But if it exists, it is necessary for each to have some magnitude and thickness, and for the one part of it to be away from the other. And the same argument holds about the part out in front; for that too will have magnitude and a part of it will be out in front. Indeed it is the same thing to say this once and to go on saying it always; for no such part of it will be last, nor will there not be one part related to another.

Thus if there are many things, it is necessary that they are both small and large: so small as not to have magnitude [the conclusion of argument (C)], so large as to be unlimited [the conclusion of argument (E)].

In argument (E) Zeno relies on the earlier argument (D), and the claim (ID) that if anything is divisible, then whatever is extended is divisible.

Each unit of a plurality must have some magnitude: Zeno argued in (D) that what has no magnitude does not exist, so units without magnitude would not exist and could not compose a plurality. But according to (ID) any product of division which has magnitude is divisible, and the products of that further division would have magnitude (since according to argument (D) they would not exist otherwise). This line of argument can be repeated endlessly. Zeno draws two related conclusions in argument (E), deriving the second from the first:

(E1) Any unit will contain an unlimited *number* of parts.
(E2) unit will be of an unlimited *size*.

Argument (E) can be blocked at different stages. First (E1) might be denied, on the ground that divisions can be carried on indefinitely but cannot be completed. (ID) entitles Zeno to argue that

(4) Given any finite *N* a magnitude admits of more than *N* divisions and contains more than *N* (non-overlapping) parts.

But (4) is not equivalent to, and does not entail

(5) A magnitude admits of an infinite number of divisions, and contains an infinite number of (non-overlapping) parts.

and it is (5) that is required for (E1).

An alternative response would be to allow that (E1) is true, although harmless, and to deny (E2). This response involves a distinction between two types of division (and part). A ‘partial’ division (P-division) of a magnitude would be a division into halves, followed by a division of one of those halves into two quarters, followed by a division of one of those quarters into two eighths,… At any stage only some of the possible divisions of equal-sized parts are made; the products of a completed P-division would include some P-parts that could be further divided. A ‘total’ division (T-division) would be a division into halves, followed by a division of both halves into four quarters, followed by a division of all those quarters into eight eighths,… At any stage all possible divisions of equal sized parts are made; if a T-division could be completed, all the divisions that could have been made would have been made. At any stage of a division the T-parts produced will be of equal size, whereas the P-parts will be of different size.

Zeno probably gets from (E1) to (E2) via an assumption about addition (ADD):

The sum of an infinite number of parts, each having a positive magnitude, is an infinite magnitude.

But (ADD) is not unrestrictedly true. In particular, it would be false of an infinite number of P-parts whose magnitudes decreased in a regular progression. Replacing (ADD) with (ADD′)

The sum of an infinite number of parts, each having an *equal* positive magnitude is an infinite magnitude.

gives something which is unrestrictedly true, but (ADD′) will not license the move from (E1) to (E2) if the parts to which (E1) refers are P-parts, since P-parts are not of equal magnitude.

The orthodoxy is that Zeno’s argument (E) does introduce P-parts. However, it is easy enough to reformulate

Zeno's argument in terms of T-divisions and T-parts (Simplicius, *On Aristotle's Physics* 139.26-140.6 in Lee 1936: §2). There are two ways of responding to argument (E), if it is thus reformulated, although neither of these appealed to ancient thinkers.

First, it could be claimed that even if a P-division could be completed, a T-division could *not* be. The completability of a T-division cannot be inferred from the completability of a P-division, since there would be more T-parts produced by a completed T-division than there are P-parts produced by a completed P-division: there would be a denumerable infinity ($\aleph_0$) of P-parts, but a super-denumerable infinity($2^{\aleph_0}$) of T-parts (since at the first (pre-division) stage there would be 1 P-part and 1 T-part, at the second stage 2 P-parts and 2 T-parts, at the third stage 3 P-parts and 4 T-parts… *n*th stage *n* P-parts and 2^{n-1} T-parts). A proof that not all infinities are of the same size awaited the work of Georg Cantor in the nineteenth century (see Cantor's Theorem; Continuum Hypothesis, the §2; Infinity §1).

An alternative response would be to allow that a T-division can be completed, and accept that the T-parts that result have equal, although *zero* magnitude, but to deny that it follows that the original magnitude composed of those T-parts would have no magnitude. None of those in the ancient world who considered Zenonian arguments in terms of T-divisions found this solution attractive, and the exposition by its modern champions requires sophisticated mathematical resources.

5 The Dichotomy

We now move from Zeno's arguments against plurality to those concerning motion. The Dichotomy is probably the best known of these. It is reported by Aristotle (*Physics* 239b11-13).

(F) [The Dichotomy] asserts the non-existence of motion on the ground that that which is in locomotion must arrive at the half-way stage before it reaches the goal.

Zeno's aim is to redescribe motion in such a way that it can be shown to be impossible. It is impossible to complete an arbitrary journey from A to B - to start at A, move to B, and then stop, for

(F1) A journey from A to B is a series of sub-journeys with no last member: from A to $\frac{1}{2}\mathrm{AB}$, from $\frac{1}{2}\mathrm{AB}$ to $\frac{3}{4}\mathrm{AB}, \ldots.$

and

(F2) It is impossible to complete a series of sub-journeys with no last member.

It would equally be possible to specify instead a series of sub-journeys with no *first* member, from A to $\frac{1}{2}\mathrm{AB}$, preceded by A to $\frac{1}{4}\mathrm{AB}$,…, allege a corresponding impossibility.

The form of argument is valid: if doing *X* is doing *Y*, and doing *Y* is impossible, then doing *X* is impossible. Zeno needs to establish both that some redescription of a journey from A to B, such as (F1) provides, is acceptable; and that a journey so redescribed is impossible, as (F2) alleges. There are, correspondingly, two main strategies for avoiding Zeno's conclusion: rejection of (F1), and rejection of (F2).

A particularly brusque rejection of (F1) is the view that there are minimal distances (*d*) which do not admit of further division, so that there is a last sub-journey, from $\mathrm{B}-d$ to B (and a first, from A to $\mathrm{A}+d$). Although there is little evidence of spatial atomism among Presocratics, a thorough-going spatial atomism is found later in Diodorus Cronus (§2). Plato's successor Xenocrates (§2) may also have adopted this position. But the costs of this strategy are high: for example, as Aristotle pointed out, the mathematical consequences are severe (all lines, for instance, will be commeasurable).

If a denial of (F1) is not feasible, there are further alternatives. One is a straightforward acceptance of (F1) and denial of (F2). Another is to distinguish different readings of (F1) and (F2), and deny that there is any single reading on which both are true together.

An example of the first strategy is Aristotle's claim that the distance between A and B and the time available to cover it are infinite in the same way, since both are divisible into smaller intervals without limit (*Physics* 233a24-31). This disposes of an intuition which may lie behind (F2); a runner would have insufficient time in

which to complete a series of sub-journeys with no last member. But that response will not apply to the following variant of the Dichotomy (*Physics* 263a11-23): passage of an arbitrary time interval $t_1 - t_2$ is impossible, since

(F1′) A time interval $t_1 - t_2$ is a series of sub-intervals with no last member: from t_1 to $\frac{1}{2}(t_1 - t_2)$, from $\frac{1}{2}(t_1 - t_2)$ to $\frac{3}{4}(t_1 - t_2)$,…
(F2′) Passage of a series of sub-intervals with no last member is impossible.

Aristotle's preferred response to the Dichotomy is an instance of the second strategy. He distinguishes between *actual* and *potential* sub-intervals (*Physics* 263a28-b8). An actual interval is an interval made actual by being marked out in some way from its surroundings - for example, by a runner starting and stopping, or by a division being made, at its termini. Intervals which could be, but are not, made actual are merely potential. Actual sub-journeys are journeys over actual sub-intervals. With Aristotle's distinction to appeal to, the premises of the Dichotomy can be taken in two ways: either as

(F1a) A journey from A to B is a series of actual sub-journeys with no last member.
(F2a) It is impossible to complete a series of actual sub-journeys with no last member.

or as

(F1b) A journey from A to B is a series of potential sub-journeys with no last member.
(F2b) It is impossible to complete a series of potential sub-journeys with no last member.

Aristotle's view is that Zeno fails to establish his conclusion because with neither (F1a)/(F2a) nor (F1b)/(F2b) do we have a pair of jointly true premises. (F1b) is a true anti-atomist claim: there is no sub-journey across an interval within AB that *has* to be the last, and there is no sub-journey that *could not* be broken into two further discrete sub-journeys. But (F2b) is false: there is no difficulty in completing a series of sub-journeys that is endless only in the sense that it contains no member that *has* to be the last.

On the other hand, according to Aristotle, (F2a) is true. It would be impossible, he claims, to complete a journey by marking off each of an endless series of sub-journeys: a runner stopping for $\frac{1}{2}$ minute after covering the first half of AB in $\frac{1}{2}$ minute, for $\frac{1}{4}$ minute after covering the next quarter in $\frac{1}{4}$ minute, … and for $(\frac{1}{2})^n$ minutes after covering the next $(\frac{1}{2})^n$ in $(\frac{1}{2})^n$ minutes would *not* cover AB in a staccato fashion in 2 minutes. Such cases have generated considerable discussion. But reaching agreement about these cases, and hence about (F2a), is less urgent if Aristotle's claim that (F1a) is false is both defensible and important: for in that case someone running from A to B does not have to complete a series of actual sub-journeys with no last member, and so would not be trying to do what (F2a) alleges cannot be done.

However, concentrating further on (F1a) would not be a good strategy for dealing with the Dichotomy. For Zeno's problem persists so long as there is *some* series which would have to be completed in order to get from A to B, but which cannot be completed. Suppose Zeno allows that (F1a) is false. Still, consider a series of points at which AB could be divided: $\frac{1}{2}\mathrm{AB}$, $\frac{3}{4}\mathrm{AB}$,… To get from A to B a runner will have to be next to each of those points in turn, although the runner will not stop at each point; and, given any one of those points, there is some other point the runner has to be next to before arriving at B. Here, Zeno will say, we have a series that cannot be completed because it has no last member.

Another distinction is now relevant. There are two series of points that Zeno might have in mind: either the (half-open) series

$$to1 \frac{}{2\mathrm{AB}, \frac{3}{4}\mathrm{AB}, \ldots, \frac{2^n - 1}{2^n}\mathrm{AB}, \ldots (\mathrm{S}) (\text{that is, B not included})} \mathrm{x}$$

or the (closed) series

$$to1 \frac{}{2\mathrm{AB}, \frac{3}{4}\mathrm{AB}, \ldots, \frac{2^n - 1}{2^n}\mathrm{AB}, \ldots, \mathrm{B}(\mathrm{S}') (\text{that is, B included}).} \mathrm{x}$$

Zeno alleges that it is impossible for a runner to start at A, move to B and then stop. The task which Zeno alleges to be impossible might be

(TS) Being adjacent to each member of (S), not being adjacent to any point not in (S), and then after that resting.

It is indeed impossible to complete task (TS): where would a runner who completed that task be? Furthermore, the reason it is impossible to complete (TS) is that the series (S) is a series with no last member. So if moving from A to B and then resting were a matter of completing (TS), motion from A to B would be impossible. But travelling from A to B and then resting is not a matter of performing task (TS) and doing nothing else. It is rather a matter of completing the task

(TS′) Being adjacent to each member of S′, not being adjacent to any point not in S′, and then resting.

and nothing Zeno has said shows that it is impossible to complete (TS′). For the series (S′) does have a last member (namely B), and that is just where a runner who finishes (TS′) will be. Of course Zeno may now try to introduce some other series with no last member that would, although impossible, have to be traversed in order to complete the task (TS′): for example, how can a runner complete (TS′) and get to B, since there is no last point at which the runner has to arrive just before arriving at B? But that question assumes that completing (TS′) would require completing TS and then doing one more thing (arriving at B), and that is a false assumption.

It is plain that Zeno has a strategy for keeping the Dichotomy argument going: he can look for another series which would have to be traversed in order to get from A to B, but which cannot be traversed. Neither the series of actual sub-journeys, nor the series of potential sub-journeys, nor the series of points between A and B provides him with such a series. But Zeno's strategy is open-ended, and two consequences follow from that. First, there is unlikely to be a single resolution of the Dichotomy argument: given different choices of series, it will sometimes be relevant to deny that the series chosen cannot be traversed, and sometimes to deny that it has to be traversed. Second, given the ingenuity of philosophers, there are likely to be ever more subtle redescriptions of a journey from A to B which call for ever more subtle responses.

6 The Achilles

Zeno's Achilles argument is very closely related to that of the Dichotomy. According to Aristotle (*Physics* 239b14-16),

[(G)] The second [argument concerning motion] is the so-called Achilles, and it amounts to this, that in a race the quickest runner can never overtake the slowest, since the pursuer must first reach the point where the pursued started, so that the slower must always hold a lead.

Suppose Achilles is running faster than the tortoise. Then as their runs proceed, the distance between the two will decrease, at a rate determined by their relative velocities. Let the distance between them initially be AB, and suppose their relative velocities are such that after $\frac{1}{2}$ minute it has shrunk to $\frac{1}{2}\mathrm{AB}$, after a further $\frac{1}{4}$ minute to $\frac{1}{4}\mathrm{AB}$,… and so on. Achilles' task is to complete an infinite series of lead-narrowings ($\frac{1}{2}\mathrm{AB}$, $\frac{1}{4}\mathrm{AB}$,…). This series of lead-narrowings will sum to a total distance no more than AB, and thus it is plain that as long as Achilles can traverse a distance AB in a finite time then he can close the distance between himself and the tortoise in a finite time. That is to say that as long as the Dichotomy can be resolved, the Achilles can be resolved. The resolutions will be parallel.

7 The Arrow

Aristotle (*Physics* 239b5-9, 239b30-3) reports the Arrow along with a summary response.

[(H)] Zeno argues fallaciously; for if, he says, everything always rests when it is against what is equal, and what is in locomotion is always in the now, the arrow in locomotion is motionless. But this is false, for time is not composed of indivisible 'nows', no more than is any other magnitude.

The third [argument concerning motion] is the one just mentioned, that the arrow in locomotion is at rest. This follows from assuming that time is composed of 'nows'; for if that is not granted, the conclusion will not follow.

The argument as Aristotle sets it out requires expansion:

(H1) Everything always rests when it occupies a space equal to itself.

(H2) What is moving is always in the now.
(H3) What is in the now occupies a space equal to itself.

Therefore

(H4) What is moving always occupies a space equal to itself [from (H2) and (H3)].

Therefore

(H5) What is moving is always at rest [from (H4) and (H1)].
(H6) Time is composed of indivisible nows.

Therefore

(H7) The ‘flying arrow’ does not move.

(H1) and (H2) are from Aristotle’s text. (H1) glosses the Aristotelian expression ‘is against what is equal’. (H3) is required to get from (H1) and (H2) to (H4). (H6) is included because it is mentioned by Aristotle. Some have suggested that the Aristotelian report gives only a fragment of a wider Zenonian argument; whether or not that is so, (H1)-(H7) present the core of the problem. The orthodoxy is that the phrase ‘the now’ in (H2) and (H3) is an Aristotelian way of talking about unextended temporal instants (or possibly indivisible temporal atoms); according to a less common interpretation the argument raises problems concerning the present.

One main line of approach, endorsed by Aristotle among others, is denial of (H1). Another is to deny an appropriate interpretation of (H3). Rejection of (H6) is also recommended by Aristotle: however, while (H6) may well be false, its relevance to Zeno’s argument is disputed. (H2) seems unassailable.

Aristotle denies (H1) on the grounds that ‘being at rest’ and ‘being in motion’ are defined only over temporal periods, and nothing can move or be at rest at an unextended instant of time: to be at rest is to occupy the same space for some period of time (*Physics* 239a23-b4). In that case (H1) is false since it admits of counter-instances: any object considered at an *instant* will occupy a space equal to itself at that instant, but will not be at rest at that instant. However, Zeno would accommodate this point by amending (H1) to

(H1′) Nothing moves when it occupies a space equal to itself.

and (H5) correspondingly to

(H5′) What is moving never moves.

(H1′) should be unobjectionable to Aristotle, yet (H5′) still seems dangerous.

Another way of denying (H1) would be to introduce definitions of instantaneous motion (and instantaneous rest), and consequently to reject both (H1) and (H1′). Zeno has a response. Someone who tries in this way to deny (H1) and (H1′has two options.

(6) To define motion at an instant derivatively from *motion over a period*: *A* is moving at an instant *t* as long as *A* is moving over a period containing *t*; *A* is moving over a period as long as *A* covers a distance during that period.
(7) To define motion at an instant derivatively from *location at other instants*: *A* is moving at an instant *t* as long as *A* occupies other places at all other instants within some period containing *t*.

Rejecting (H1) and (H1′) on the basis of (6) begs the question against Zeno: it is to say that an arrow is flying at *t* because *t* occurs within a period in which it is flying, and Zeno will not be impressed by such a blunt rejection of the Parmenidean world view. On the other hand, (7) allows the possibility of a quasi-Parmenidean view on which temporal process is replaced by a series of static distributions of objects to places (see Tense and temporal logic); furthermore, if instants were replaced by temporal atoms, (7) would lend support to the view of Diodorus Cronus (§2), who was widely regarded in antiquity as denying the existence of motion.

An alternative line is to challenge (H3). If read as a claim about the *present*, (H3) relies for its appeal on the assumption that the present is an unextended instant separating past and future. That assumption could be denied,

and replaced with an account of the present as a period of indeterminate extension - although Zeno could reasonably demand some independent support for such a revisionary view of the present. Still, if an instantaneous present is rejected, (H3) would no longer be guaranteed. Zeno’s Arrow argument would be no more persuasive than the following: no object can have a size; for every object is, for some place, located *here*; any extended place can be split into part *there* and part *there*; so *here* must be extensionless; so any object located *here* must be extensionless. That argument rests on the false assumption that ‘here’ must be an extensionless location.

Aristotle has another response to Zeno’s argument, which is to reject (H6). Some commentators doubt the relevance of (H6) to Zeno’s argument; and (H6) embodies something which Aristotle is keen to emphasize independently of his concern with Zeno’s arguments. Aristotle’s point is that motion and rest are characteristics which apply irreducibly over periods of time. In much the same way, colour is a feature of extended surfaces which cannot be reduced to features of extensionless points: it would not be legitimate to argue that, since no body is coloured at an extensionless point, there are no coloured bodies.

8 The Moving Rows

Aristotle’s report of the Moving Rows is condensed, and a diagram, such as is provided by Alexander of Aphrodisias, is useful (Aristotle, *Physics* 239b33-40a1).

[(J)] The fourth [argument about motion] is the one about equal bodies which move in opposite directions past equal bodies in a stadium at equal speed, the one row from the end of the stadium and the other from the middle - in which he thinks it follows that half the time is equal to double.

Figure 1			$A1$	$A2$	$A3$	$A4$		
	$B4$	$B3$	$B2$	$B1$				
					$C1$	$C2$	$C3$	$C4$

Figure 2	$A1$	$A2$	$A3$	$A4$
	$B4$	$B3$	$B2$	$B1$
	$C1$	$C2$	$C3$	$C4$

The *A*s, *B*s and *C*s are of the same size; the *A*s are stationary, and the *B*s and *C*s are moving at equal speeds in opposite directions. The two examples above show how the positions of the bodies change over the time taken for *B*1 to go past two of the *A*s. Neither the significance of the conclusion, that ‘half the time is equal to double’, nor Zeno’s route to that conclusion are altogether clear. Suppose Zeno assumed that

(J1) A body moving at a certain velocity will take the same time to pass two bodies of the same size, even if one is stationary and one moving.

He could then argue in this way. Suppose the time it takes *B*1 to move from its position in the first example to its position in the second example is *t*. In the second example *B*1 has arrived at *C*4, and so

(J2) The time it takes *B*1 to move from its starting position to *C*4 is *t*.

But it is equally true that *t* is the time taken for *B*1 to get from its starting position to *A*2; then by assumption (J1) it will take *B*1 the same time (*t*) to get from its starting position to *C*2 (since *C*1 and *C*2 are together equal in size to *A*1 and *A*2); and therefore it will take *B*1 twice as long to get to *C*4 (since *C*3 and *C*4 together represent an extra distance to be covered which is equal in size to *C*1 and *C*2, and *B*1 continues at a constant speed); therefore

(J3) The time it takes *B*1 to move from its starting position to *C*4 is 2*t*.

(J2) and (J3) together entail

(J4) $t = 2t$

If Aristotle’s diagnosis is based on an accurate presentation of Zeno’s argument, then Zeno’s argument is weak. For (J1) is plainly false, and in the absence of (J1) no contradiction threatens: *B*1 passes twice as many *C*s as *A*s in a given period of time, but this is because the *C*s but not the *A*s are moving relative to *B*1. Some have found a

better argument for Zeno by supposing that the bodies in question are atomic, moving in an atomically structured time. It is not likely, though, that Zeno had such a target in mind; and it is of course possible that Zeno offered the occasional weak argument. It is also possible that Zeno sought to direct attention to the relativity of velocity and motion, and by doing so to impugn their status: a similar suspicion of what is relative is found slightly later in the atomist Democritus, who downgraded sensible properties such as sweet, bitter, hot and cold because they depended as much on the perceiver as on what is perceived (see Democritus §5).

9 Two other arguments

Zeno's reputation is founded on his arguments concerning plurality and motion. However, there are ancient reports (of doubtful reliability) which identify two further arguments as Zenonian. Aristotle twice mentions a Zenonian argument against the existence of place (*Physics* 209a23-5, 210b22-4, Lee §38), resting on the thought that if place exists it would itself have to be in a place. Another Zenonian argument mentioned by Aristotle poses this problem (250a19-24; expanded by Simplicius, *On Aristotle's Physics* 1108.18-28, Lee §38, who identifies Protagoras as its target): how can smooth variations give rise to radical and discontinuous differences? When a large mass of corn hits the ground it makes a noise, so that a fraction of that mass (for example, one ten-thousandth of a single grain) should make a fraction of the noise - but in fact it makes no noise at all. The second of these arguments in particular raises large issues, which cannot be adequately considered here.

Zermelo, Ernst (1871-1953)

The German mathematician Ernst Zermelo is today best known for his axiomatization of set theory (1908b), presented in the spirit of Hilbert's early axiomatic programme. Originally working in the calculus of variations and mathematical physics, Zermelo concentrated on set theory after proving that every set can be well-ordered (1904). His proof, based on the axiom of choice, provoked a lively controversy. In the 1930s Zermelo worked on infinitary logic, trying to overcome Gödel's incompleteness results.

1 Life

Ernst Zermelo studied mathematics, physics and philosophy at the universities of Berlin, Halle and Freiburg. In 1894 he obtained his doctorate from Berlin with a dissertation taking a Weierstrassian approach to the calculus of variations (see Analysis, philosophical issues in). He became an assistant to Max Planck, but in 1897 he went to the University of Göttingen where he finished his *Habilitation* thesis on hydrodynamics in 1899. He began to teach as a *Privatdozent* at Göttingen and was made a titular professor in 1905. In 1910 he accepted a chair of mathematics at the University of Zurich, but resigned in 1916 because of poor health. After 1921 he lived in retirement in Freiburg, where he became honorary professor of mathematics in 1926. After National Socialistic students had denounced him, he resigned to avoid being dismissed. Following the war he was reinstated but, then almost blind, was never again able to teach.

2 Work

After working in the calculus of variations, thermodynamics and statistical mechanics, Zermelo published his first paper on set theory, concerning the addition of transfinite cardinals (see Set theory §3), in 1902. His later work on set theory can be seen as a contribution to the lively discussion of Cantor's continuum hypothesis. Cantor had conjectured that every infinite subset of the continuum is either denumerable or has the power of the continuum (1878: 257; see Continuum hypothesis). In 1900, in his seminal Paris lecture, 'Mathematische Probleme', Hilbert had emphasized the importance of proving Cantor's 'remarkable assertion' that every set could be well-ordered, and that this fact could be used to prove the continuum hypothesis. In 1904 Zermelo succeeded in proving the well-ordering theorem using a construction of sets by transfinite recursion justified by appeal to what would later be called the 'axiom of choice' (see Axiom of choice). This proof, together with the axiom of choice, was rejected by many mathematicians working in foundations. Zermelo responded to his critics with a new proof, retaining the axiom of choice and emphasizing the purely formal character of the well-ordering, which has nothing to do with 'spatiotemporal arrangements' (1908a: 107). He accompanied his proof by a polemical discussion of objections, arguing that his critics also used infinite numbers of arbitrary choices and that he was by no means the first to use the axiom.

Zermelo shifted his emphasis to set theory both because of the heavy reactions to his former proof and also because of the fact that set theory began to move into the focus of foundational research in Göttingen. The sensation caused by the publication of the set-theoretical paradoxes by Bertrand Russell in 1903 led to a revision of David Hilbert's early axiomatic programme (see Paradoxes of set and property; Hilbert's programme and formalism). Although Zermelo had independently found a similar paradox in 1899 or 1900, it was only with Russell's publications that it became evident that Hilbert's programme, which centred on the problem of proving the consistency of arithmetic, had to take into account the consistency of logic itself; and that set theory was necessary for an axiomatization of arithmetic. In this vein Zermelo began working on a new axiomatization of set theory by 1905 (see Moore 1982: 152-7), though, unable to find a consistency proof for it, he delayed publication until 1908. In the published version (1908b: 262-7) Zermelo stated seven axioms: the axiom of choice, the power set axiom and the axioms of extensionality, elementary sets, separation, union and infinity (see Set theory §1; Set theory, different systems of). He mentioned the lack of a consistency proof for this set of axioms, but remarked that it was not subject to Russell's paradox since from his axiom of separation (if a propositional function $\mathrm{E}(x)$ is definite for a set *M*, then there is a subset M_{E} containing precisely those elements *x* of *M* for which $\mathrm{E}(x)$ is true) it follows that a universal set cannot be derived.

Zermelo's axiomatization underwent several revisions, the most important of which was the addition of the axiom of replacement, formulated by Dmitry Mirimanoff (1917), Thoralf Skolem (1923) and Abraham Fraenkel (1922),

and adopted by Zermelo in Fraenkel's version. Skolem gave the first first-order exposition of Zermelo's set theory, which grew into the Zermelo-Fraenkel set theory (ZF) of today.

Subsequent work was spawned by Zermelo's opposition to the 'Skolemist' interpretation of the Löwenheim-Skolem theorem, according to which '*every* mathematical theory, even set theory, can be realized in a denumerable model' (Zermelo 1931: 85; original emphasis). In 1929 Zermelo gave a second-order axiomatization of the property of definiteness which was presupposed by the axiom of separation and which was the feature of his set theory at which most of the criticism had been directed. In response to his critics (among them especially Thoralf Skolem), Zermelo created in 1930 a new (supplemented) version of ZF - ZF' - which was formed by dropping the axiom of infinity and reclassifying the axiom of choice as a principle of the background logic. He also introduced the axiom of foundation, which prohibits infinitely descending chains of membership (1930: 31). This led to the introduction of well-founded sets which were used to define a cumulative type hierarchy, consisting of layers (indexed by ordinals) which are sets made up of objects from previous layers. At the annual meeting of the Deutsche Mathematiker-Vereinigung at Bad Elster on 15 September 1931, Zermelo used this hierarchy to propose a new infinitary mathematical logic without any quantifiers (see Moore 1980: 124-8). He claimed, contrary to what was suggested by Gödel's then just recently announced work, that this logic would decide every proposition. These ideas did not find the audience that Zermelo had hoped for, although there are several similarities to today's systems of set theory (see Lavine 1994).

Zhang Zai (1020-77)

Zhang Zai was a seminal neo-Confucian cosmologist and ethical thinker. Like Zhou Dunyi and Shao Yong, he was inspired by the Yijing (Book of Changes) and its commentaries; unlike them, he worked out a conception based solely on the concept of qi *(cosmic vapour). He espoused an ethical vision, global in spirit, that greatly enhanced the moral significance of Confucianism.*

Zhang Zai was born in Changan, China, and grew up in an age of intellectual ferment. He studied Buddhism, Daoism and even military strategy before embarking on a serious study of the Confucian classics and joining the ranks of the neo-Confucians. He focused his learning on the *Zhongyong (Doctrine of the Mean)* and the *Yijing (Book of Changes)* (see Zhongyong; Yijing). Later, when he lectured on the *Yijing* in the capital, his students included such luminaries as the historian Sima Guang and the philosopher brothers Cheng Hao and Cheng Yi. Zhang held occasional government positions but, since he opposed the reforms of Wang Anshi (1021-86), he balanced his government service with teaching at home. He died of illness while travelling home from the capital.

In 1070, Zhang had an uncanny dream in which he envisaged the formation of the cosmos. He articulated this vision in the book *Zhengmeng (Correcting Youthful Ignorance)*, an attempt to explain the cosmos and man, and even such fundamental terms as the supreme polarity (*taiji*) and the Way (*dao*), in terms of *qi* states, permutations and processes. To many interpreters, this approach resembles reductive materialism, but *qi* in the Chinese view is a fluid proto-material which gives rise to phenomena of all sorts, mental and spiritual as well as physical (see Qi). Hence, unlike reductive materialism, there is no attempt to deny any realms of phenomena such as the mental. However, because Zhang's *qi*-based theory did not seem to provide an adequate account of order in the cosmos and the constancy of human values, it was long overshadowed by the *li* (pattern) based thought of the Cheng brothers and Zhu Xi (see Li). Centuries later, Wang Fuzhi, believing that the Cheng-Zhu idea of *li* was arbitrary and inflexible and thus lent itself to rigid conservatism, strongly advocated a revival of Zhang Zai's teachings. Chinese scholars today tend to praise Zhang's thought as anti-metaphysical and proto-scientific.

Cheng Yi accused Zhang's book of a false objectivism that diluted the Confucian moral message, which Cheng deemed purely a matter of subjective intuition. On his part, Zhang postulated *qi* as the common substance to ground a universal morality of sympathy and benevolence. Whatever the merits of this idea, he wrote the noblest and most compelling moral tract to come out of the neo-Confucian movement, the *Ximing (Western Inscription)*, which reads, in part:

> Heaven is my father and Earth is my mother, and even such a small creature as I find an intimate place in their midst.
>
> Therefore that which fills the universe I regard as my body and that which directs the universe I consider as my nature.
>
> All people are my brothers and sisters, and all things are my companions.
>
> … Wealth, honour, blessings, and benefits are meant for the enrichment of my life, while poverty, humble station, and sorrow are meant to help my fulfillment.
>
> In life I follow and serve [Heaven and Earth]. In death I will be at peace.

(*Ximing* in Chan (1963): 497-8)

Zheng Xuan (AD 127-200)

Zheng Xuan, perhaps the most influential commentator on the Confucian classics, is widely credited with constructing both a compelling unitary vision of Chinese civilization and a hierarchy of written authorities which upheld the supremacy of the five Confucian classics as infallible guides to morality and history. Inevitably, scholars (including Zheng's many critics) have 'read' early Chinese society through the filter of Zheng's surviving commentaries, which ultimately superseded earlier divergent scholastic traditions.

Of the nearly sixty texts attributed to Zheng, only four complete works remain: commentaries on each of the three Rites Classics - the *Liji (Book of Rites)*, *Zhouli (Rites of Zhou)* and *Yili (Ceremony and Rites)* - and a subcommentary appended to the Mao *Shijing (Book of Songs)*. Judging from these works, Zheng Xuan's genius lay in his ability to embody a great deal of information in succinct comments; in imitation of the heroic sages of antiquity, Zheng aimed to 'raise a single principle that applies to a myriad cases… so as to minimize [the need for independent] thought'. Thus, Zheng's commentaries frequently include general statements recapitulating the main principles that underpin the entire Confucian tradition, which he tied to philological explanations based on archaic or regional pronunciations (complementing the *Shuowen* dictionary's emphasis on the visual components of Chinese characters). Zheng's commentaries also relate material from different classical authorities, so that puzzling passages may be solved by 'internal evidence' provided by the sages; in addition, Han customs, popular expressions and even artefacts are described whenever they shed light on ancient practices. As a result, Zheng's annotations go far beyond the standard pre-Han commentarial format (which usually presented glosses in the form '*X* means *Y*'), without lapsing into the prolixity of many Han scholarly explications.

Collected fragments of early polemical texts offer tantalizing clues about three famous disputes (with Xu Shen, He Xiu and Wang Su) involving Zheng and his disciples. Often misinterpreted, these disputes did not centre on either the authenticity of the apocryphal (*wei*) texts or allegiances to New Script/Old Script (*jinwen/guwen*) 'schools'. As Zheng cited the apocrypha only when other early sources corroborate their accounts, his reliance on the apocrypha was quite conservative by contemporary standards. Further, after twenty years devoted to the study of both Old and New Script texts, Zheng was determined to find common ground in competing theories about the classics. Basically, Zheng deplored the literalist approach of Xu and He, which would require the rejection of parts of the sacred canon. Zheng further objected to He's elevation of the *Gongyangzhuan (Gongyang Commentary)* to the *Chunqiu (Spring and Autumn Annals)* to virtual canonical status (see Chinese Classics); in Zheng's view, none of the three major commentaries to the *Chunqiu* could rival the 'subtle message' (*weiyan*) of Confucius' own masterwork. A third dispute, continued over centuries by the disciples of Zheng and Wang Su, was apparently prompted by Zheng's failure to preserve *jiafa* (discrete scholastic lines) and by Wang's pronounced royalist sentiments. The very virulence of the attacks launched against Zheng only attests to his seminal influence on classical studies.

Although Zheng established the basic conventions for critical scholarship in China, modern scholarship discounts his famous 'proofs' for the single, divine origin for the classics and their apocrypha, and also questions Zheng's dating of important works, including the *Zhouli (Rites of Zhou)*. Such empirical errors clearly stem from Zheng's fervent desire to reconcile contradictory passages. Zheng's attempts to shore up the political system of late Han dynasty certainly coloured his commentaries; hence his continual reiteration of ritual's function in preserving the *status quo* and his rejection of the usual ethical dimensions of key status terms (such as 'ruler' and 'gentleman'). However, researchers readily acknowledge Zheng's remarkable erudition with regard to scribal errors, loan characters, dialect pronunciations, script variants, authorial mood and literary context. The ease with which Zheng moves between different disciplines and interpretations confirms his place as a *tongru* (polymath), though it surely also signals a loss of faith in the earlier formulations of Confucian orthodoxy.

Zhi

In classical Chinese philosophy, zhi*, conventionally translated as 'knowing', is not so much a knowing 'what', which provides some understanding of the natural world, as it is a knowing 'how' to be adept in relationships, and 'how', in optimizing the possibilities that these relations provide, to develop trust in their viability. The cluster of terms that define knowing are thus programmatic and exhortative, encouraging the quality of the roles and associations that define us. Propositions may be true, but it is more important that husbands and friends be so.*

If the major concern in the Chinese tradition is for *how* rather than *what* - finding a way (*dao*) rather than seeking the Truth - this can only mean that most of the theoretical and practical correlates of the search for truth will themselves be absent, with the consequence that the shape of the Chinese cultural sensibility may be expected to be radically distinct from that of Western culture. Rather than a vocabulary of truth and falsity, right and wrong, good and evil - terms that speak to the 'whatness' of things - we find pervasively the language of harmony and disorder, genuineness and hypocrisy, trust and dissimulation, adeptness and ineptness; terms which reflect the priority of the continuity that obtains among things, and the quality of that continuity. That is, 'how well' do things hang together?

In contrast to Western philosophy that began from the decontextualizing metaphysical sensibilities of the classical Greeks, the Chinese tradition is resolutely historicist. Reason is a series of historical instances of reasonableness; culture is a specific historical pattern of human flourishing; logic is the internal coherence of this particular human narrative; knowledge, always local and site-specific, is knowing how to make one's way smoothly and without obstruction. In fact, the performative and perlocutionary entailments of 'knowing' often make 'realizing', in the sense of 'making real', a better translation of this term. Truth is proximate: it is the capacity to foster productive relationships that begin with the maintenance of one's own integrity and extend to the enhancement of one's own natural, social and cultural contexts.

Truth-seekers want finally to get to the bottom line, to establish facts, principles and theories which characterize the way things are. Truth-seekers see a world divided into the way things appear and the way they truly are, and continually try to come up with propositions - true sentences - that describe the reality of things in an accurate manner.

Way-seekers have dramatically different interests. They accept that they live in a human world and seek those forms of action which promote harmonious social existence. For the Way-seekers, truth is most importantly a quality of persons rather than of propositions. Truth as 'way' refers to the genuineness and integrity of a fully functioning person - a *true* human being. To 'know' the way is to walk it, and to become wise in doing so.

Zhi Dun (AD 314-66)

Buddhist monk and specialist on the Zhuangzi, *Zhi Dun was active in the* xuanxue *or 'learning of the mysterious' salons of the Eastern Jin regime in southeastern China. For him, the sage described by the* Zhuangzi *and Buddhist texts alike was a great man who knows the ways of heaven triumphantly and responds to beings in perfect freedom. Zhi Dun was also known for his interpretation of emptiness and his expansion of the concept of li ('order' or 'pattern') into an underlying metaphysical principle.*

Zhi Dun is the primary representative of a new social development in Chinese history, when numbers of men sought purely spiritual learning in monasteries apart from the secular realm, and when the religion became widely accepted at the highest levels of Chinese society, among both men and women. He was ordained in AD 338 after studying the Perfection of Wisdom (*prajñā pāramitā*) so popular at the time, and died after spending several years teaching at the imperial court. At some point he wrote a commentary on the 'Free and Easy Wandering' chapter of the *Zhuangzi*, now lost. A homely man known for his waspish tongue and trenchant characterizations of people, he was friendly with some of the most prominent men of his day, including the Daoists Wang Xizhi (a famous calligrapher) and Sun Chuo. Xi Chao, a layman whose summary of Buddhist doctrine survives, was his student. Zhi Dun was a devotee of Amitābha, the Buddha of the Pure Land, and wrote a commentary on a scripture devoted to meditation on breathing.

The most significant element in Zhi Dun's thought was his understanding of the sage or perfect man, which he described on the basis of both the *Zhuangzi* and Buddhist texts (see Zhuangzi). He disagreed with the contemporary interpretation of the *Zhuangzi* which held that everyone should follow one's own nature and be happy, which was too amoral and deterministic for his Buddhist inclinations. Instead, the sage was a supramundane embodiment of truth, able to respond to the myriad demands of sentient beings without moving himself. Just as the myriad sounds of the world would cause a bell to reverberate, so would the sage resonate according to the needs of beings, yet the various words and teachings spoken by the sage would not be identical to his own inner wisdom. Implicit in this concept of the sage is the sense that there is an absolute (*tathatā*, but often rendered as *li*) underlying all things (see Li). Zhi Dun was one of the earliest figures to explain Buddhism in terms of being and nonbeing (*you* and *wu*) (see You- wu).

Zhi Dun's understanding of emptiness is described as 'form as such'; known only through very sketchy fragments, it apparently refers to the existence of form through a plethora of co-dependent causes. He denied that there was any permanent substrate underlying form, and he realized that form was both equivalent to and different from emptiness. (Here form represents *se*, or *rūpa* in Sanskrit, the first of the five *skandhas* or constituents of the human being; it thus stands as part for the whole of conditioned phenomena.) Based on the scanty evidence extant, Zhi Dun's theory of emptiness seems to contradict his redefinition of *li* as a metaphysical substrate underlying phenomena.

Zhiyi (538-97)

The Chinese Buddhist monk Zhiyi is revered as the chief architect of the Tiantai school of Buddhism, one of the most distinctive and influential systems of Mahāyāna Buddhist thought and practice to take shape on East Asian soil. His systematization of the Tientai teachings marked the emergence of the first major indigenous articulation of Buddhist thought and practice in China. This is considered an important watershed in the development of the East Asian Buddhist tradition, for it effectively brought to a close some five centuries of Chinese dependence on Indian Buddhist traditions of exegesis and opened the way to creation of the distinctive forms of scriptural hermeneutics and motifs of religious life that we regard as representative of East Asian Buddhism today.

Historically, Zhiyi's religious career spans the key transition between the last years of the strife-torn North-South Dynasties Period (317-581) and the lengthy era of political unification ushered in by the Sui (589-618) and Tang dynasties (620-906). Zhiyi himself is often credited with producing a synthesis of different regional currents of medieval Buddhism that is the religious analogue to the reintegration achieved by the Tang ruling house in the social and cultural spheres.

Born of a well-to-do family distantly connected with the Liang ruling house, Zhiyi's life was abruptly shattered at the age of 17 with the death of his parents and the sack of his home city, Jiangling, at the hands of the Western Wei army. Deeply shaken, he resolved shortly thereafter to become a Buddhist monk. Over the next few years he wandered through Hubei and Henan in search of a suitable teacher, eventually settling down with Nanyue Huisi (515-77), the spirited master of meditation who would later be listed as Zhiyi's predecessor in the Tiantai patriarchal lineage. Under Huisi's guidance, Zhiyi achieved his first major spiritual awakening and was exposed to the rudimentary system of doctrinal classification around which he would fashion his own mature scheme of Tiantai thought and practice.

In 568, at his teacher's urging, Zhiyi proceeded to the southern capital of Jinling to begin his own teaching career. He was received with enthusiasm and over the next seven or eight years acquired a large following among the aristocracy and Buddhist clergy of the capital, including members of the Chen ruling house. However, despite his growing popularity, Zhiyi became increasingly troubled by the limitations that such a bustling environment placed on his ability to train disciples and pursue his own religious practice. This led him in 575 to leave the capital and retire with a small group of students to the isolation of Mount Tiantai in central Zhejiang province. The decade of quiet religious pursuit that followed is regarded as a turning point in Zhiyi's spiritual and intellectual development, marked above all by the maturation of the distinctive system of doctrine and practice that we identify with Tiantai.

Between 585 and his death in 597, Zhiyi again threw himself into the bustling life of court and capital. During this period he enjoyed not only the support of the last Chen ruler but, when the Chen fell to the Sui in 581, also gained the enthusiastic patronage of prince Yang Guang, the man who would ultimately succeed the first Sui emperor, Wen (or Yang Jian), as the ill-fated Emperor Yang. Through the influence of Yang Guang and the Sui court, Zhiyi built Yuquan Monastery in Hubei and laid plans for the expansion of monastic facilities on Mount Tiantai (the construction of the famous Guoqing Monastery, realized several years after Zhiyi's death). With the death of Yang Guang and the collapse of the Sui in 617, Tiantai access to imperial patronage was severed. Nevertheless, over the two centuries that followed the Guoqing and Yuquan communities continued to function as vibrant centres of Tiantai learning. Their traditions influenced not only the formation of Tang Buddhism at large but also found their way to Korea and Japan, giving rise to the powerful Chôntae and Tendai orders in those two countries (see Buddhist philosophy, Japanese; Buddhist philosophy, Korean).

Despite the significance that we attribute to Zhiyi as *de facto* founder of the Tiantai tradition, it would be misleading to say that he intentionally set out to create a new Buddhist school. Like Confucius many centuries before him, Zhiyi thought of himself more as a reclaimer of the old than a creator of the new. Throughout Zhiyi's writings one finds a deep sense of anxiety over the petty rivalries and clerical malaise that he perceived among his Buddhist compatriots. As one who believed profoundly in the inherent unity of the Buddha's enlightened vision and received word, his synthesis was nothing short of an effort to rescue the 'true Dharma' or 'true intent of the Buddha' from the fragmentation and moral ossification that he saw around him. Against this backdrop, Zhiyi

develops a distinctive vision of the Buddha as master of both the transcendent and mundane worlds, whose special genius lies not so much in his grasp of the ineffable reality of enlightenment as in the compassion and pedagogical skill to reach out and guide beings effectively to this end. Zhiyi defines the Tiantai religious path as a twofold discipline involving the seamless integration of meditative experience (*guan*) with comprehensive study of received scriptural tradition (*jiao*). To serve these ends, he developed detailed schemes for meditative practice as well as classification of scripture and its contents (see Buddhist philosophy, Chinese).

Tiantai tradition credits Zhiyi with a prodigious literary output - over fifty works in nearly two hundred fascicles, according to the most fanciful count. However, critical research has significantly reduced this number. Of the works that we may safely connect with Zhiyi, only a handful were written by the man himself; the majority were taken down and edited from his lectures by various disciples, notably his attendant Guanding (561-632). Three treatises in particular have been singled out by later tradition as offering the definitive statement of Tiantai teaching: the *Fahua xuanyi (Profound Meaning of the Lotus Sutra)*, *Fahua wenju (Words and Phrases of the Lotus Sutra)*, and *Mohe zhiguan (Great Calming and Contemplation)*. The first two are synthetic and interlinear commentaries to the *Lotus Sutra*, the scripture hailed by Tiantai tradition as the culmination of the Buddha's career, in which the Buddha professed with the greatest clarity and finality the harmonious unity of his *dharma* (see Buddha). The *Mohe zhiguan* is a work of meditation dedicated to the 'perfect and sudden' contemplation. Although no explicit connection with the *Lotus Sutra* is developed in this text, Tiantai tradition regards it as the practical counterpart to the sublime doctrinal vision spelled out in the two *Lotus* commentaries. All three treatises bear the mark of Guanding's editorial hand. Among contemporary scholars there has developed considerable debate as to how much of their final form is the work of Zhiyi or of Guanding.

Zhongyong

The Zhongyong (Doctrine of the Mean) has traditionally been ascribed to Zisi, the grandson of Confucius and the indirect teacher of Mencius. Although this ascription has been challenged by modern critical scholarship since the turn of the twentieth century, recent archaeological finds indicate that the traditional view is not without textual base. If the Zhongyong actually predated the Mengzi, it seems that a significant portion of the Liji (Book of Rites), of which the Daxue (Great Learning) and Zhongyong are chapters, contains documents of the fifth century BC*. This fact alone merits a fundamental restructuring of classical Confucian chronology and reinterpretation of the Mencian line of the Confucian tradition.*

The Chinese title of the essay is composed of the characters ‘centrality’ (*zhong*) and ‘normality’ or ‘commonality’ (*yong*). *Zhongyong (Doctrine of the Mean)*, suggesting the basic moral idea of moderation, balance and suitability, conveys a profoundly meaningful notion of humanity as both an anthropological and cosmological ideal. Centrality and commonality in the *Zhongyong* connotes that ordinary human virtues such as filial piety, honesty, reciprocity, and benevolence, if thoroughly comprehended and fully embodied in our action, can help us to understand not only ourselves but also nature and Heaven. This faith in the improvability of the human condition through self-effort and in the human capacity to know and realize the truth and reality of Heaven through self-knowledge leads to the theory and practice that philosophy as a way of life addresses the ontological issues of who we are, what we know, how we should act and what we can hope (see Self-cultivation in Chinese philosophy).

Intent on relating what is most essential in humanity to the underlying reality of the cosmos, the *Zhongyong* is organized around three integrated visions: the profound person, the fiduciary community and moral metaphysics. Since human nature is endowed by the decree of Heaven, there is a wellspring of creativity inherent in the structure of human existence here and now. If we allow that wellspring to flow naturally, we will find the most authentic way of learning to be human. Indeed, the ultimate concern of education is none other than the cultivation of the human way. Implicit in this seemingly optimistic vision of self-realization are four inseparable dimensions of human flourishing: self, community, nature and Heaven. Learning to be human entails the fruitful interplay between self and community (family, society, nation and the world), the dynamic equilibrium between the human species and nature and the creative fidelity between the human heart-and-mind and the way of Heaven (see Tian; Xin). This requires constant attention to even the minute details in our daily living and ceaseless effort in elevating our levels of consciousness and self-reflexivity.

Profound people optimize their capacity to realize the full potential inherent in human nature. Such a project of self-realization, if shared as a joint venture for mutual exhortation, will form a discourse fellowship which may serve as a standard of inspiration for the creation of a fiduciary community. A community, based upon mutual trust of its members for the sake of completing the human project as co-creator of the cosmic process, is a ‘holy rite’ in which the sanctity of the earth, the sacredness of the body and the beatitude of the family enable a concrete living person to become not only a moral agent but also an anthropocosmic presence:

> Only those who thoroughly embody sincerity can fully realize their own nature. If they can fully realize their own nature, they can fully realize human nature. If they can fully realize human nature, they can fully realize the nature of all things. If they can fully realize the nature of all things, they can participate in the transforming and nourishing processes of Heaven and Earth. If they can participate in the transforming processes of Heaven and Earth, they can form a trinity with Heaven and Earth.

Zhou Dunyi (1017-73)

*Zhou Dunyi was the father of Chinese neo-Confucianism. His oracular presentation of the notions of supreme polarity (*taiji*),* yin *and* yang*, and the five phases to explain the formation of the cosmos and sagehood became enshrined by Zhu Xi as the authoritative neo-Confucian view.*

Born in Daozhou, China, Zhou served with distinction in a series of official posts from about 1040 to 1072 but is famed for his love for nature and his secluded cottage near a waterfall on Lu Mountain. There he wrote two visionary tracts on metaphysics, sagehood and ethics. His contemporaries Shao Yong and Zhang Zai pursued similar themes, but lacked Zhou's clear synthetic vision and subtle articulation. Cheng Hao and Cheng Yi, who went on to develop neo-Confucianism into an intellectual movement, studied under Zhou but later concealed his formative influence.

Zhou's synoptic essay *Taiji tushuo (Explanation of the Diagram of the Supreme Polarity)* presents a dynamic conception of reality. It begins with an account of the formation of the cosmos in levels from elementary forces to complex phenomena, and ends with an account of the sage as a reflection of the cosmos. The text opens with an intriguing dialectical proposition that even now arouses discussion and debate: 'Free from any polarity (*wuji*), and yet the supreme polarity (*taiji*)!' Taking *wuji* as the Daoist 'utmost of non-being', Lu Xiangshan (1139-93) saw this proposition as an illicit attempt to bifurcate basic reality into two distinct categories. His contemporary Zhu Xi countered that *wuji* here does not refer to a positive concept. It simply indicates that *taiji* (supreme polarity) is not a discrete, locatable entity; it is the primal pattern of change, that which describes the intercourse between *yin* and *yang* and thus pervades reality. Next, the *Taiji tushuo* goes on to describe how *yin-yang* intercourse gives rise to the five phases - earth, wood, fire, water, metal - which in turn engender 'heaven, earth and the myriad things', the empirical world (see Yin-yang).

Humanity reflects this fecund cosmos, but most consummately in the person of the sage, 'whose virtue matches that of heaven and earth, whose brilliance matches that of the sun and moon, whose order matches that of the four seasons, and whose fortunes match those of the gods'. In the *Tongshu (Penetrating the Book of Changes)*, Zhou describes sagehood, self-cultivation and related concepts. The distinguishing virtue of sagehood is cheng (sincerity, authenticity). The sage authentically manifests the creative virtues of the cosmos. Through this sincerity, he abides by the mean and acts according to the cardinal virtues adumbrated by Confucius. The sage is thus one who acts in an upright manner yet spontaneously and without deliberation. Those who aspire to this sphere must, above all, cultivate a pure, tranquil mind (see Confucian philosophy, Chinese).

Dedicated to this view, Zhou impressed others with his distinctive manner. The poet Huang Tingjian (1045-1105) lauded Zhou as 'a man of lofty character, fresh and vigorous as a breeze in the sunlight…. Modest in striving for renown yet ardent in seeking self-realization, he is indifferent to worldly success yet steadfast in friendship' (*Songshi* (History of the Song Dynasty) 427: 3).

Zhu Xi (1130-1200)

The Chinese neo-Confucian philosopher Zhu Xi was a consummate scholar and classicist as well as a superb critical and synthetic thinker. He fused the ideas of the seminal eleventh-century thinkers Shao Yong, Zhou Tunyi, Zhang Zai, Cheng Hao and Cheng Yi into a grand philosophical synthesis. In addition, by effectively editing and annotating the essential classical Confucian texts - the Analects of Confucius - the Mengzi of Mencius, the Daxue (Great Learning) and the Zhongyong (Doctrine of the Mean) - as the Four Books, Zhu worked out a lasting renewal of the Confucian project.

Zhu Xi was born in Youqi in Fujian province, China. He was a precocious child who at five asked what lay beyond heaven and at eight grasped the significance of the *Xiaojing (Book of Filial Piety)*. Reared in the company of scholars, Zhu obtained the *jinshi* degree (presented scholar degree, the highest level qualifying degree in the examination system) at nineteen. He nurtured an eclectic interest in Daoism and Chan Buddhism until becoming a student of Li Tong (1093-1163) in 1160. Li persuaded him of the superiority of Confucianism, to which he devoted himself for the rest of his life. He held various prefectural administrative posts but, disapproving of court policy, preferred temple guardianships, sinecures that gave him leisure to read, write and teach. He thus became a highly productive scholar who made lasting contributions to classical studies, historiography and literary criticism as well as to philosophy. He also was a master prose stylist and poet.

As a renowned master, Zhu taught the classics and neo-Confucianism. His teachings are preserved in the *Zhuzi yulei (Classified Dialogues of Master Zhu)*. An assiduous teacher and scholar, Zhu continued to work right up to his death. He set rigorous new standards for textual criticism and philosophic thought; his idealistic spirit and productive life remain an inspiration to this day in East Asia.

Zhu Xi created an impressive metaphysical synthesis that has been compared broadly to the systems of such cardinal Western thinkers as Plato, Aristotle, Thomas Aquinas and A.N. Whitehead. Zhu developed Zhou Dunyi's dynamic conception of reality, as depicted in the *Taiji tu (Diagram of the Supreme Polarity)* (see Zhou Dunyi), in order to conceive the Cheng brothers' concept of *li* (pattern) and Zhang Zai's notion of *qi* (cosmic vapour) as organically integrated (see Cheng Hao; Cheng Yi; Zhang Zai). In Zhou's treatise *Taiji tushuo (Diagram Explaining the Supreme Ultimate)*, Zhu found a viable account of the formation of the cosmos in levels: from the original unformed *qi* and the supreme polarity (*taiji*), to *yin, yang* and the five phases - earth, wood, fire, water and metal - down to 'heaven, earth and the myriad things', the empirical world. Zhu blended this conception with ideas from the *Yijing (Book of Changes)* and its commentaries (see Yijing) to set forth a comprehensive philosophy of cosmic creativity and to ground the Confucian notions of human nature, self-cultivation and self-realization. Zhu's penchant for thinking in polarities, however, has stirred critics to regard him as a dualist.

On the basis of this complex conception of reality, Zhu set forth a sophisticated theory of human nature that accounts for the possibility of evil as well as of sagehood. In this view, whereas people are fundamentally good - that is, sensitive and well-disposed - how one manifests this original nature will be conditioned by one's specific *qi* make-up, one's personality and intelligence, and level of attainment. The differences in people's disposition, character and aptitude for self-realization are regarded as due to variations in their *qi*-endowments.

Not registering the complexity of human nature and the wide variation of individual differences, the preceding generations of neo-Confucian scholars had advocated straightforward methods of self-cultivation to purify the mind and elicit the original nature; they understood this to constitute self-realization (see Xing; Self-cultivation in Chinese philosophy). Zhu's teacher Li Tong had advocated a form of meditation called 'quiet-sitting', the efficacy of which Zhu doubted from the outset. Later Zhu held discussions with Zhang Shi, a disciple of Hu Hong, who advocated introspection in action. At first, Zhu accepted this approach, but he soon found that introspection in action is not viable, for such introspection cannot inform action in the desired way; it in fact impedes effective action.

Zhu Xi's solution was a two-pronged approach to cultivation: to nurture a sense of reverence (*jing*) while investigating things to explore their patterns (*li*). Reverence purifies the mind, attunes one to the promptings of the original nature and impels one to act with appropriateness. At the same time, by grasping the patterns which

constitute the world and upright interpersonal relations, one learns more about appropriate conduct. The mind which is imbued with reverence and comprehends these patterns will develop into a good will.

In later years, Zhu regarded this conception of cultivation as insufficiently motivational. He then argued that, like Confucius, one must at the outset establish the resolve to realize the Confucian ideals (see Confucian philosophy, Chinese). Zhu believed that such resolve lends an overriding purpose to one's cultivation effort and thus preserves one's motivation. This was a theme which Wang Yangming developed effectively some three centuries later.

In *Renshuo (A Treatise on Humanity)*, Zhu articulates the classical Confucian ideal of humanity (*ren*) in cosmic and human perspective. At the same time, he effectively criticizes competing accounts of *ren* on logical and semantic grounds. Zhu associates *ren* with cosmic creativity; at root, *ren* is the impulse of 'heaven and earth' to produce things. It is manifested in the cycle of seasons and the fecundity of nature. This impulse is instilled in all creatures, but in man it is sublimated into the virtue of *ren*, which when fully realized involves being diligent and responsible to others. Zhu similarly correlated the four stages of production in nature - origination, growth, flourishing and firmness - mentioned in the *Yijing* with the four cardinal virtues enunciated by Confucius - humanity, appropriateness, ritual action and wisdom - in order to portray the realized person as a vital participant in cosmic creativity as well as a positive catalyst for the well-being and self-realization of others. On this basis, Zhu went on to formulate the authoritative definition of *ren* for the tradition as 'the character of mind' and 'the pattern of love'. *Ren* thus grounds the fundamental disposition of mind as commiserative and describes the core of moral self-realization as love for others, appropriately manifested.

Zhuangzi

The Zhuangzi is a Daoist text usually associated with 'Master Zhuang' (fourth century BC), also known as Zhuang Zhou. Scholarly consensus regards the thirty-three chapters of this text to be composite, containing passages that offer different and sometimes even contradictory interpretations of basic Daoist tenets. The opening seven 'inner chapters' are traditionally thought to be from the hand of Master Zhuang himself, while the remaining 'outer' and 'miscellaneous' chapters are taken to be later elaborations and commentary by members of what retrospectively can be called a Master Zhuang school, or better, lineage. As a philosophical text, the Zhuangzi is for the most part addressed to the project of personal realization, and only derivatively concerned about social and political order. As one of the finest pieces of literature in the classical Chinese corpus, the Zhuangzi is itself an object lesson in marshalling every trope and literary device available to provide rhetorically charged flashes of insight into the most creative way to live one's life in the world.

The consummate human being in *Zhuangzi* is called the 'Authentic Person' (*zhenren*), and consummate 'ethical' concerns have to do with the contributions one is able to make to the *ethos* or total character of one's world. Thus, 'ethics' in a Daoist sense would involve not simply moral judgments, but the total character of the person as it is constructed in their social and natural environments (see Daoist philosophy). This total character is the changing lineaments of habit and disposition that include not only what might be deemed 'good' or 'moral' but the full complement of the qualities which constitute the personal, social and natural fabric of one's existence. Having said this, it must be clear that any 'ethical' judgments in the narrow sense are going to be derived from aesthetic sensibilities - the intensity, integrity and appropriateness that one detail has for its environing elements as interpreted from some particular perspective. Thus, no clear direction into ethics, social, political, and environmental philosophy, exists in this tradition.

To the extent that Daoism is normative and prescriptive (and it certainly is), it is so not by articulating rules to follow or asserting the existence of some underlying moral principles, but by describing the conduct of an achieved human being - the Authentic Person - as a recommended object of emulation. The model for this human ideal, in turn, is the orderly, elegant and harmonious processes of nature. Throughout the philosophical Daoist corpus, there is a 'grand' analogy established in the shared vocabulary used to describe the conduct of the achieved human being on the one hand, and the productive harmony achieved in the mutual accommodations of natural phenomena on the other.

Among the *Zhuangzi*'s central concerns is human creativity. To be fully integrative, inchoate individuals must overcome any sense of discreteness and disjunction with their environments to contribute personally to the emerging pattern and regularity of the world around them. This creativity can be compromised, however, where one attempts to express one's unique particularity in a 'dis-integrative' way that fails to accommodate the mutuality and interdependence of other things. This diminution in creative possibilities can be brought about either by interpreting one's environs reductionistically through one's own fixed conceptual structures and values, thereby impoverishing context in service to oneself, or by allowing oneself to be shaped wholly by context without contributing one's own uniqueness, thereby abnegating oneself in service to context.

The choice of 'authentic' rather than 'true' or 'real' as a translation for '*zhen*' in *zhenren* is calculated. With the same root as 'author', 'authentic' captures the primacy given to the creative contribution of the particular person in authoring the world. It further registers this contribution as what is most fundamentally 'real' and 'true'. It is because of the primacy of the 'authorship' of the 'authentic person' in creating human order that the *Zhuangzi* insists: 'there must be the Authentic Person before there can be authentic knowledge'. To 'know' a world is to 'realize' it in the sense of making it real. This claim made at the beginning of *Zhuangzi* 6 means that 'knowing' is not simply a cognitive exercise, the grasping of some pre-existing reality. Rather, 'knowing' is also performative: one must participate actively in the 'realization' of one's world through one's own 'self-disclosure' (*ziran*). 'Knowing' for the Daoist, in addition to being cognitive, is profoundly experiential and collaborative.

In translating (*ziran*) as 'self-disclosure', we must bear in mind that 'self' is always 'in context'. For the Daoist, like the classical Chinese tradition broadly, there is a priority of situation over agency, and a priority of change over form. The particular self is thus neither discrete nor superordinate, but is always continuous with its ever

changing world. It is sponsored by, and ultimately reflects in itself, the full consequence of existence. 'Self' is an individuated focus (*de*) in the ongoing field of the social, natural and cultural processes (*dao*) that articulate our world.

The Authentic Person's activity, characterized as *wuwei* (non-assertive action) is defined by flexibility, efficacy and non-contentiousness. One collaborates with one's social and natural environments, serving as frictionless ground for their self-disclosure, and they reciprocally for one's own. Because one develops a sense of identity and continuity with the process as a whole, one is calm and imperturbable. This sense of continuity enables one to exist beyond the plethora of disintegrative dualisms - self and other, creator and creature, life and death, reality and appearance - and to overcome death not by escaping to some more 'real' existence, but by coming to realize and to celebrate the mutually entailing identity of oneself and one's world.

Early Daoism has had an incalculable influence on the development of Chinese philosophy and culture. Second in influence only to the Confucian school, the classical Daoist philosophers in many ways have been construed as both a critique on and a complement to the more conservative, regulatory precepts of their Confucian rivals. When Buddhism entered China in the second century AD, Buddhist adepts appropriated many of the ideas and vocabularies of indigenous Daoism as a sympathetic language through which to express a fundamentally foreign system of thought. In so doing, they made Buddhist ideas more palatable to the Chinese audience, but at the same time, they also set Buddhism on a course of irrevocable Sinicization.

Zionism

Zionism, the idea of Jewish nationality in its modern form, emerged towards the end of the nineteenth century, several decades after nationalism had taken hold among most European peoples. The term denotes the ideology as well as the movement(s) whose goal is re-establishment of the Jewish people as a nation in its homeland in Palestine. Unlike many other movements of national liberation, Zionism seeks not the removal of a colonial regime but the return of a people to its land. The most ancient roots of this aspiration were religious, but many forms of modern Zionism shed the messianic and eschatological elements of the two-thousand-year-old hope in favour of more immediate political and social aims that were often philosophically shaped.

1 Moses Hess

The most important philosophical forerunner of Zionism was Moses Hess (1812-75). Against the background of the unification of Italy in 1859, Hess saw the quest of the Jewish people for renewed nationhood as ‘the last national problem’. Philosophically, his vision was shaped by Hegelian philosophy (see Hegelianism), an enthusiastic response to the philosophy of Spinoza, and the Fichtean idea of *Bestimmung*, destiny, an idea that conveyed at once a sense of mission and of objective historical laws setting the parameters of that mission’s fulfilment. The historic mission of the Jewish people was to spread the idea of universal human harmony throughout the world and so to contribute to the global struggle for social and national liberation. But that ancient mission could be achieved only if the people of Israel could re-establish its own state.

Hess’s metaphysical conceptualization of Israel’s mission among the nations did not diminish the concreteness of his attention to the anomalies of diaspora Jewish life. His prescriptions for renewal and normalization in the historic Jewish homeland anticipated many of the ideas proclaimed half a century later by the labour Zionist movement. A friend and co-worker of the young Karl Marx, Hess was a pioneer both of socialism and of Zionism, and particularly of socialist Zionism. His *Rom und Jerusalem (Rome and Jerusalem)* (1862) evoked no positive responses when first published. Only some thirty years later, with the founding of the Zionist organization, was the book retrieved from oblivion and made integral to Zionist ideology. Although unsystematic and often favouring intuition and sentiment over rigorous argument as a guide to its speculation, the work endures as a monument and anchor of philosophical Zionism.

2 Hibbat-Zion

Zionist ideas were spread through eastern Europe by the Hibbat-Zion movement, which drew its inspiration from Jewish tradition. Religious longing for ‘the Land’ joined with disappointment in the fruits of the emancipation promised by Enlightenment rhetoric. These emotions far outweighed any philosophical deliberations in the rise of Zionism as a popular ideology. But Leopold Pinsker and Ahad Ha’am did give a philosophical bent to Hibbat-Zion.

Pinsker (1821-91) began his celebrated pamphlet *Auto-Emancipation* (1882) with an analysis of anti-Semitism. Like Hess, he argued that the Jewish people is a distinct ethnicity that cannot be assimilated - not that Jews will not integrate into the societies in which they live but that in the long run they are not tolerated, not allowed to do so. Hatred towards Jews, ‘Judophobia’, Pinsker argued, was the chief cause of Jewish separateness (see Anti-Semitism), and the perennial isolation of Jews as outsiders can be overcome only when Jews become once again a proper nation with a state of their own, regaining their own homeland and the chance to live in peace and dignity like any other nation. Among his chief goads in writing *Auto-Emancipation*, Pinsker confesses, were Spinoza’s parallel but more negatively couched remarks at the end of the third chapter of the *Tractatus Theologico-politicus*.

Theodor Herzl, the founder of political Zionism, devoted his *Der Judenstaat (The Jewish State)* (1896) to elaborating Pinsker’s thesis that ‘the Jewish problem’ could be solved only if the Jews were no longer a national anomaly. Yet Herzl’s role as a visionary statesman and powerful journalist did not make him a philosopher.

Ahad Ha’am (Asher Ginzberg, 1856-1927) is a thinker of a different stamp. Although no systematic philosopher, he was deeply influenced by nineteenth-century evolutionist ideas, especially those of Herbert Spencer. His outlook never became the main road of Zionist thinking, but it had a powerful impact on Zionist theory. Jewish

particularity, he argued, is grounded in a spontaneous sentiment of national belonging. The sentiment, akin to family ties, needs no theoretical justification or argument. For such feelings are prior to consciousness itself. A nation's 'will to live' is a resultant of every individual's will to live. But the Jewish situation engenders problems of special complexity - most portentously, that of assimilation. A 'spiritual centre' in Palestine, Ahad Ha'am argued, would constitute an effective barrier against assimilation: here Judaism could be preserved, and the identity of the Jews of the diaspora would be assured by the ideas radiating from this centre. Tragically, however, Ahad Ha'am neglected the underlying problem of anti-Semitism and its pressures towards assimilation, isolation and, in the extreme, annihilation of the Jews.

3 Land and language

Jacob Klatzkin (1882-1948), whose intellectual work dealt mainly with medieval Jewish philosophy and Spinoza, also elaborated a philosophical Jewish nationalism. He castigated the tendency of Reform Jews to transform Judaism into a merely spiritual idea. This 'trying to be a Jew without being Jewish' (*Jude-Sein ohne Jüdisch-Sein*) only paves the way to assimilation. But Orthodoxy is equally flawed. Where the reformers seemed to reduce Judaism to a spiritual mission, Orthodoxy reduced Jewishness to mere norms of practice - just another subjective criterion of Jewishness. If Jewishness is to be a durable fact, Klatzkin argued, it cannot be a matter of religion or morality. For to be a Jew no longer entails a particular religious or spiritual commitment. Rather, the subjective historical will to belong to the Jewish people finds its objective expression in the fact of national belonging. The spiritual influence of Judaism on other religions and on Western culture was undeniable, and Klatzkin did not deny the distinctive spirit of Judaism and of Jewish ethics and values. But he bitterly opposed efforts to make these the national paradigms or foci. Jewish nationalism must be rooted in the objective ground of land and language. The very survival of the Jewish people demanded that the Jewish people abandon its inveterate intellectualizing and spiritualizing and resume national life in its own homeland, with its own language.

Klatzkin's arguments were fraught with conceptual shortcomings. His thesis that 'only forms can serve as national criteria', for example, led him to define 'land' and 'language' as national forms, denying them material content! But even such philosophically dubious moves do not diminish the importance of his recognition that the will to settle on one's own land and speak one's own language is vital to Jewish peoplehood. Nor did Klatzkin underrate such external factors as hatred directed against Jews as such, the persecution and discrimination that Ahad Ha'am had underrated. A mere spiritual centre in Palestine would not be enough. Only a national home would resolve the Jewish question.

The inference was clear: the modern definition of a Jew is secular. Only those whose homeland is Palestine and whose language is Hebrew (or who aspire to achieve this) can be Jews. Klatzkin's arbitrary definition of Jewishness in effect excludes all Jews who continue to live outside Israel and do not intend to settle there. It was perhaps his exclusion of the bulk of diaspora Jewry that in the end marginalized Klatzkin as a Zionist thinker and led to his playing only a minor role in the unfolding of Zionist thought.

4 Socialist Zionism

Among the Zionist thinkers who deserve philosophical attention, Nahman Syrkin (1868-1924) developed an early synthesis of socialism and Zionism, and Ber Norochov (1881-1917) went further in the same direction. Borochov grounded his reflections in a distinctive version of the Marxist idea of class struggle. Without a country of their own, he reasoned, Jews remain a powerless minority, confined to 'unproductive' and peripheral pursuits, petty and secondary trades. Barred from heavy industry, 'the axle of the historical wheel', they cannot become true proletarians and so lack a 'strategic base' for carrying forward the class struggle. Jewish 'proletarization' will occur only when the 'inverted pyramid' of Jewish economic life is returned to its broad base; and only in their own country will Jewish workers be able to struggle successfully against the bourgeoisie and win their way to a healthy and independent economic life. Socialism and Zionism are thus necessarily intertwined. Borochov, accordingly, unlike many a Marxist and bourgeois Jewish thinker, condemned assimilation: not only will it never succeed but even its pursuit is a dangerous illusion, since it turns Jews away from the struggle for national emancipation. Efforts to emigrate from Europe to other countries such as those of North and South America, similarly, will only perpetuate the anomaly of the diaspora. What Jews must do is return to their own country, Palestine. Many of Borochov's Marxist notions about Jewish nationhood now require critical re-examination. But his thinking had a powerful impact on labour Zionism and endures in the recognition that labour must be the foundation of the

restored Jewish nation.

Among the non-Marxist socialist Zionists, A.D. Gordon, Berl Katznelson and their disciples were especially important. For them Zionism begins in a voluntary act of the individual, affirming the dignity of physical labour and of ties to the soil. These rather agrarian thinkers aspired to create a new Jew to replace the dispossessed Jews of the diaspora. J.H. Brenner and others, influenced by Nietzsche, similarly denounced what they saw as a diaspora mentality and demanded a radical break with the Jewish spiritual heritage. But here, as with Klatzkin, the exclusionary tendency in the end proved more limiting to the influence of its authors than to the scope and appeal of the Zionist idea.

5 Martin Buber

Finally, Martin Buber played an important role in shaping Zionist consciousness among young Jews in western Europe, especially through his famous *Drei Reden über das Judentum (Three Addresses on Judaism)* (1909-11). In time his Zionist thought was overshadowed by his studies of Hasidism and the Bible and above all by his dialogical philosophy and social thinking. But Buber's Zionism carried forward some of the utopian socialist ideas developed by A.D. Gordon and the anarchist G. Landauer. It grew into what he called Hebrew Humanism, which found the differentia of Zionism from other national movements in its idealism. In keeping with his philosophical vision and with the universalism that he drew from the wellsprings of Jewish moral thought, Buber was among the first and most important Zionist theorists seriously to address the issue of Jewish-Arab relations. His philosophical humanism led him to insist that Jews and Arabs should live together in peace and harmony in a common homeland. But at the time of their enunciation these claims were not taken up by most Zionists as integral to the Zionist programme.

The foregoing examples of philosophical Zionism, exemplified in the writings of its 'founding fathers' are hardly a comprehensive listing. Many other philosophers have engaged in theoretical exploration of the promise and problems of Zionism - among them, J. Kaufmann, J. Klausner, F. Weltsch, M. Brod, N. Rotenstreich, Y. Leibowitz, M.M. Kaplan, A.J. Heschel, A. Neher and E. Levinas. Still other names would need to be mentioned if one were to address the politically divergent views within Zionism, such as Zionist Revisionism. But despite the importance and originality of the living exponents of Zionist thinking, they all belong to a generation for whom Zionism is a *fait accompli*, a living reality, whose theorists, perforce, must now regard not only its 'roots' but - to continue the metaphor - the cultivation of its varied and multi-coloured 'flowers'.

On the theoretico-philosophical plane, a controversy has arisen recently concerning whether contemporary Judaism and the State of Israel belong already to a post-Zionist era, characterized by coexistence between the State of Israel and diaspora Judaism. The majority of the present-day immigrants to Israel (mainly from Russia and Ethiopia) do not migrate out of Zionist conviction but for pragmatic reasons - to exchange their adverse living conditions for better ones. This, however, reaffirms the Zionist idea that a Jewish homeland is the solution to their existential problems in the diaspora.

Zongmi (780-841)

Zongmi was a Chinese Buddhist Chan (Zen) and Huayan scholar, traditionally reckoned as the fifth 'patriarch' both in the Heze line of Southern Chan and in the Huayan scholastic tradition. He is important for his revision of Huayan doctrine, his commentaries to the Yuanjuejing (Scripture of Perfect Enlightenment), his accounts of Chan teachings and his contribution to the theory of the essential unity of the three teachings of Buddhism, Confucianism and Daoism.

Zongmi (more fully, Guifeng Zongmi) was born into a family of local prominence in a town in the southwestern province of Sichuan. As a youth he received a traditional education in the Confucian classics; he became interested in Buddhism as an adolescent, but continued his Confucian studies at a local academy in preparation for the imperial examinations that would open the door to an official career. In 804, however, he met the Chan master Daoyuan and was so impressed that he abandoned his worldly ambitions to become the latter's disciple. Later, while still a novice monk, he experienced his first awakening after reading a few pages of the *Yuanjuejing (Scripture of Perfect Enlightenment)*. Zongmi continued his Chan study under Daoyuan, receiving full ordination in 807.

In 810, Zongmi was introduced to the commentary and subcommentary to the *Avatamsaka Sūtra* written by the eminent Huayan scholar Chengguan (738-839). These works so impressed him that in 812 he became a disciple of Chengguan and studied intensively with him for two years in the imperial capital of Changan. He subsequently embarked on an extensive reading of the Buddhist canon. In 816 he left the capital to continue his research at various temples on Mount Zhongnan, where he spent much of the remainder of his life. This period of prolonged study bore fruit in a series of definitive commentaries and subcommentaries to the *Yuanjuejing* completed during 823 and 824.

In 828 Zongmi was invited to court, where he was honoured with a purple robe and the title of 'Great Worthy'. He returned to Mount Zhongnan a year or two later, where he carried on an active correspondence with a number of the leading scholar-officials he had met in Changan. He also wrote two major works on Chan, *Chanyuan zhuquanji duxu (Preface to the Collected Writings on the Source of Chan)* and *Zhonghua chuanxindi chanmen shizi chengxi tu (Chart of the Master Disciple Succession within the Chan School That Transmits the Mind Ground in China)*. His scholarly activity came to an abrupt end in 835, when he became implicated in an abortive attempt to oust the eunuchs from power at court. Afterwards he withdrew from public life, and nothing further is known about him until his death in 841.

Zongmi's work can be seen as the culmination of a number of themes important in the evolution of the medieval Chinese Buddhist scholastic enterprise. By simplifying the doctrinal complexities of earlier scholasticism, it achieved a greater coherence and systematic unity. Philosophically, it illustrates the tendency within Chinese Buddhism to de-emphasize the teaching of emptiness, which undermines ontological speculation (see Buddhist concept of emptiness), by elaborating the ontological implications within the Indian Buddhist doctrine of the *tathāgatagarbha* (the potentiality for Buddhahood inherent in all sentient beings, more popularly referred to as Buddha-nature) (see Buddhist philosophy, Chinese).

In the context of the Huayan tradition, Zongmi's systematic classification of Buddhist teachings marks a significant revision of the tradition from its classical formulation by Fazang (643-712). Most significantly, Zongmi omitted the Perfect Teaching, which Fazang had ranked highest in his fivefold scheme, and, in its stead he raised to pre-eminence the teaching that Fazang had merely ranked third. The teaching that was displaced had elaborated the unimpeded interrelation of all phenomena, and was precisely that which Fazang had taken to express the most profound insight of the Buddha, which was revealed exclusively in the *Avataṃsaka Sūtra* and was therefore the basis of the Huayan tradition's claim to represent the most exalted teaching of Buddhism. Textually, Zongmi's rearrangement of Buddhist teachings signals his displacement of the *Avataṃsaka Sūtra* in favour of the *Yuanjuejing* as the ultimate basis of Huayan thought; doctrinally, it reveals his emphasis on the *tathāgatagarbha* as the most fundamental teaching of the Buddha.

The revision that Zongmi made in Huayan doctrinal classification can be understood as part of his effort to provide

an ontological basis for Buddhist practice. His revalorization of Huayan thought in turn points back to his involvement with, and reaction to, various developments that had taken place within Chan. The iconoclastic rhetoric of the radical movements that had gained currency within Chinese Chan during the later part of the Tang dynasty (618-907) could easily be misinterpreted in antinomian ways that denied the need for spiritual cultivation and moral discipline. Having grown up and received his early Chan training in Sichuan, an area in which the most extreme of these movements flourished in the late eighth and early ninth centuries, Zongmi was particularly sensitive to such ethical dangers. Zongmi's concern with the ethical implications of Chan teachings, moreover, reflects the lasting influence of his early study of the Confucian classics.

The importance of Confucianism for Zongmi can be seen in his attempt to develop a syncretic framework in which Confucian moral teachings could be integrated within Buddhism. He thus claimed that the differences among the three teachings of Buddhism, Confucianism and Daoism were a matter of expedients, being a function of the particular historical circumstances in which they were taught and having nothing to do with level of understanding attained by each of the three sages (Buddha, Confucius and Laozi). Zongmi's writings demonstrate his life-long effort to justify the values that he had learned as a youth in terms of the discrepant claims of the religion to which he had converted as an adult.

Zoroastrianism

Zarathushtra, better known to the Classical and modern world in the Greek form of his name 'Zoroaster', revealed his vision of truth, wisdom and justice in the verse texts known as the Gāthās (c.1200-1000 BC) and is revered by Zoroastrians as their holy prophet. The religion is correctly described as mazdāyasna, *'the worship of Ahura ('Lord') Mazdā, creator of the world and source of all goodness. Since the Avestan word* mazdā *means 'wise, wisdom', Zoroastrians see their prophet as the original* philosophos, *'lover of wisdom'. Zarathushtra's message is primarily ethical and rationalistic. Zoroastrianism teaches a life based on (1) the avoidance of evil, through rigorous discrimination between good and evil, and (2) the service of wisdom through the cherishing of seven ideals. These latter are personified as seven immortal, beneficent spirits: Ahura Mazdāhimself, conceived as the creative 'holy' spirit; Sublime Truth; Virtuous Power; Good Purpose/Mind; Beneficent Piety; Wholeness/Health and, finally, Immortality. Evil originates neither from God nor from his creatures, but from a wholly other source, personified as Angra Mainyu, the 'Hostile Spirit', whose existence is ritually and doctrinally rejected as being pretended and parasitic. Real existence is solely the domain of Ahura Mazdāand his creation; Angra Mainyu and his demons are actually states of negativity, denial or, as the religion puts it, 'the Lie'. Thus the charge that the religion is ontologically dualistic is no more true than it is of other systems which conceive of good and evil as being in fundamental opposition. Equally, the allegation that its theology is ditheistic or polytheistic is a misunderstanding of the Zoroastrian theological and ritual tradition. The influence which this religion has exerted on classical philosophy and the thought and practice of Judaism, Christianity and Islam is being reappraised by scholars in modern times.*

1 Prophet and community

The Iranian prophet Zarathushtra founded one of the world's oldest and most enduring religions many centuries before Jesus of Nazareth and several millennia before Nietzsche's usurpation of the name (see Nietzsche, F. §10). Zoroastrianism was the religion of pre-Islamic Iran and survives to this day in one of the world's smallest and most widely dispersed communities, the Iranian Zardushtis and their Indian 'Parsi' co-religionists. In the classical world and in pre-modern Europe, the figure of Zoroaster has been associated, in esoteric and popular circles, with a mysterious and arcane wisdom, but the actual religious tradition which bears his name is generally unknown, or underestimated as to its historical importance.

Zoroastrianism was the principal religion of the Iranians under the Achaemenian, Parthian and Sasanian empires for a thousand years from the sixth century BC, and as the state church of the Sasanian kings in their long wars against Rome it clashed directly with Christianity. It was disestablished by the Islamic conquest of Iran in the mid-seventh century AD, and since then Zoroastrians have lived as a dispossessed religious minority in their homeland. As a result of religious persecution, a number of them migrated to northwest India in the tenth century AD and established the Parsi ('Persian') community. Their descendants flourished in the Indian milieu, first as agriculturalists, then as traders, merchants and entrepreneurs in the colonial and postcolonial periods. Zoroastrianism is an ethnic religion which generally does not accept converts; in modern times the problems of the community's demographic decline have worsened as a result of inter-marriage, secularization and emigration to Western countries from India, Pakistan and post-revolutionary Iran. The total number of Zoroastrians worldwide is reckoned to be less than 120,000.

Zarathushtra's revelation is preserved in the *Gāthās*, a small body of very ancient hymns dated by scholars as originating from the latter part of the second millennium BC and written in a northeastern Iranian language, Gāthic Avestan. The *Gāthās* are the oldest stratum of a larger scriptural canon, known collectively as the *Avesta*, which were originally transmitted orally and subsequently written down in Avestan (a language related closely to Sanskrit). As a result of the destruction of the priesthood and their lore at the hands of Alexander the Great (forever cursed by the tradition) and the later Muslim conquerors, only one fifth of the original *Avesta* survives. The *Avesta* was from ancient times accompanied by an exegetical body of texts known as the *Zand*. This *Zand* is extant now only in a later, Middle Persian language, Pahlavi, written down in its present form in the Sasanian and early Islamic periods (4th-10th centuries AD). Taken on their own, without the evidence of these later books, the *Gāthās* are difficult to interpret because of their prehistoric context and archaic symbolism: the study of the *Gāthās* continues to divide modern scholars, with regard to dating, geography and the precise nature of Zarathushtra's

teachings. However, the Zoroastrian tradition as preserved in the Avestan and Pahlavi texts gives a clearer picture of the prophet and his mission. Zarathushtra refers to himself as a priest of his ancestral religion, skilled in its ritual and teachings. Dissatisfied, however, he went in search of a nobler doctrine to deliver the world from the tyranny of oppressors and, after years spent wandering, at the age of thirty he received the first of many visions from Ahura Mazdā. His prophetic mission lasted the rest of his life, receiving and delivering the divine message to those who would listen until, as tradition says, he was killed by an assassin in his old age.

2 Cosmology and doctrine

According to Zoroastrian doctrine, before all existence there were two spirits, one good, creative of life, and beneficent; the other one evil, inimical to life, and malevolent. The two spirits are eternally opposed to one another. Ahura Mazdāis identified in the tradition with the spirit of goodness, called Spenta Mainyu, translated as ‘Holy or Beneficent Spirit’; he created first the spiritual then the physical worlds as a means of combating and finally annihilating Angra Mainyu, the ‘Hostile Spirit’. The physical world was originally perfect when created, but was invaded and is now afflicted by the Hostile Spirit. Zarathushtra urges those who will listen to choose goodness and smite evil by aligning themselves with Ahura Mazdāand his spiritual helpers, the *amesha spentas*, ‘blessed immortals’ and *yazatas* ‘[beings] worthy of worship’. Human beings have a soul, embodied in this physical world, which is part of an eternal nature that remains in the spiritual world. The human soul records a person’s acts of virtue and wickedness which will be respectively rewarded and atoned for in a spiritual state after one life in the physical state. The religion advocates purity in thought, word and deed, as Angra Mainyu and his demons benefit from all acts of wickedness and defilement of Ahura Mazdā’s creation. Human life is therefore a constant struggle for both goodness and purity. Towards the end of human history a *saoshyant*, ‘one who brings benefit’, will come to champion the victory of the righteous over the forces of evil. Time will end, there will be a resurrection of all the dead and a last judgment of all souls. A new, spiritually and physically perfect world will be made here on earth, and evil will be banished for eternity from the universe. There will be a return to the pristine perfection of the original creation, but with the fullness of physical and spiritual multiplicity of forms unafflicted by evil in a state called *Frashokereti* (‘Renovation’). The religion is thus based on a vision which is primarily soteriological and eschatological, promising deliverance from imperfection, through human effort aligned with the divine will. There is also a sophisticated philosophical theology which reflects on Zoroastrian salvation history, cosmology and ethics, contained in some of the Pahlavi books, notably the *Dēnkard*, based upon older Avestan material which is now lost.

3 Moral and physical purification

Zarathushtra’s vision became embedded in a sacramental liturgical tradition which is a continuation and elaboration of the pre-Zoroastrian cult. Scholars believe that in remote antiquity an Indo-Iranian civilization of Central Asia comprised one great cultural and linguistic group, living a semi-nomadic pastoral existence on the inner Asian steppes. Their common religious tradition would have been formed in the fourth to third millennia BC, and thus when, around 1800 BC, the Indians and Iranians separated and began to move to what are now their respective homelands, they took with them the basis of what became the related religious cultures of Brahmanism and Zoroastrianism (see Hindu philosophy). Over time they articulated their religious cult and beliefs in distinctive ways, but both share a fundamental regard for the world as *alive with divinity*, needing maintenance, through spiritual and physical acts, which refresh and reconsecrate the elements and of the cosmos as a whole. The central religious act was the rite called *yasna* in Avestan, *yajña* in Vedic Sanskrit, literally ‘act of worship’, performed in order to re-enact the primordial cosmic sacrifice by which the universe was begun. In Zoroastrianism, although it is an elaborate ceremony, it is essentially an act of reconsecration of the elements of the world: metal, water, earth, plant, animal, human and fire.

The common basis of the Indian and Iranian religious traditions is also exemplified by the cognate words of Vedic Sanskrit *ṛta* and Zoroastrian Avestan *asha*, both of which mean ‘order, law, truth’, the highest principle in the universe. *Asha* also means spiritual and moral righteousness: the righteous man is called *ashavan*, as distinct from the *dregvant*, the one who adheres to evil (Avestan *drug*). Zarathushtra’s message is a transformation of the old Indo-Iranian religion, which emphasizes as paramount the *human* (as opposed to superhuman) ethical responsibility for the maintenance of the world through the fight against the forces of disorder. The beliefs and practices of Zoroastrianism all aim at achieving a harmony of the human world with that of nature, physical,

spiritual and divine. The Blessed Immortals named in the *Gāthās* were associated with the elements of the physical world, not as merely symbolic correspondences but as the potent invisible realities which protect and inhabit the elements of the physical world. The living world of plants and animals, and the rest of the natural world, is felt to be alive with divinity, not in a pantheistic sense of a 'nature-cult', but because the physical and spiritual realms of existence are thought to be mutually sustained and protected. This is the basis of the moral and physical code of purity in Zoroastrianism. Fire, for example, is revered not in itself but as the manifestation of the Blessed Immortal Asha Vahishta 'Best Righteousness/Law', and has the epithet 'truth-strong fire'. The dubbing of Zoroastrians as 'Fire-worshippers' is an old and obvious misunderstanding of the religion.

Zoroastrians understand purity as both moral and physical: physical purity is an essential requirement for any religious or moral action. Although the physical world is vulnerable to pollution, it must be emphasized that it is not intrinsically polluted or inferior to the spiritual state. The traditional daily regime of purification for the laity and particularly the priesthood might be thought strenuous by non-Zoroastrians, but this is seen as enhancing the state of persons in physicality, not diminishing their condition of embodiment. As far as is known there have never been any tendencies towards the ascetic practices of self-mortification found in other religions. Little has been said in this entry of the complex ritual and liturgy of the traditional practice of priesthood and laity. Modernist tendencies in the contemporary community question the value of the traditional forms of practice, while conservative elements adhere to them as unchangeable. Underlying all forms of Zoroastrianism, however, is the belief that the example of Zarathushtra and his *spenta daēna* ('virtuous conception') of humanity express a true human potentiality to reflect the divine nature.
